AMERICAN MEDICAL ASSOCIATION, CHICAGO 10, 1948

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1948-1949

HEADQUARTERS OF THE ASSOCIATION, 535 N. DEARBORN ST., CHICAGO

GENERAL OFFICERS

PRESIDENT—R. L. SENSENICH	South Bend, Ind.
PRESIDENT-ELECT—ERNEST E. IRONS	Chicago
VICE PRESIDENT—ROY W. FOUTS	Chicago
SECRETARY AND GENERAL MANAGER—GEORGE F. LULL	Chicago
ASSISTANT SECRETARY—ERNEST B. HOWARD	Chicago
TREASURER—J. J. MOORE	Chicago
SPEAKER, HOUSE OF DELEGATES—FRANCIS F. BORZELL	Philadelphia
VICE SPEAKER, HOUSE OF DELEGATES—JAMES R. REULING	Bayside, N. Y.
EDITOR—MORRIS FISHBEIN	Chicago
BUSINESS MANAGER—THOMAS R. GARDINER	Chicago

BOARD OF TRUSTEES

Louis H. Bauer	Hempstead, N. Y., 1949
E. L. Henderson, Chairman	Louisville, Ky., 1949
John H. Fitzgibbon	Portland, Ore., 1950
James R. Miller	Hartford, Conn., 1950
Walter B. Martin	Norfolk, Va., 1951
Dwight H. Murray	Napa, Calif., 1952
Edward J. McCormick	Toledo, Ohio, 1952
Edwin S. Hamilton	Kankakee, Ill., 1953
Gunnar Gundersen	La Crosse, Wis., 1953

JUDICIAL COUNCIL

Edward R. Cunniffe, Chairman	New York, 1949
Louis A. Buie	Rochester, Minn., 1950
Walter F. Donaldson	Pittsburgh, 1951
H. L. Pearson Jr.	Miami, 1952
John H. O'Shea	Spokane, Wash., 1953
George F. Lull, Secretary, ex officio	Chicago

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Reginald Fitz	Boston, 1949
Russell L. Haden	Cleveland, 1950
William S. Middleton	Madison, Wis., 1951
H. G. Weiskotten, Chairman	

	Syracuse, N. Y., 1952
Victor Johnson	Rochester, Minn., 1953
W. L. Pressly	Due West, S. C., 1954
Harvey B. Stone	Baltimore, 1955
Donald G. Anderson, Secretary	Chicago

COUNCIL ON SCIENTIFIC ASSEMBLY

Charles H. Phifer	Chicago, 1949
Henry R. Viets, Chairman	Boston, 1950
L. W. Larson	Bismarck, N. D., 1951
Stanley P. Reimann	Philadelphia 1952
Alphonse McMahon	St. Louis, 1953

AND EX OFFICIO

The President-Elect, the Editor and the Secretary of the Association

COUNCIL ON MEDICAL SERVICE

Elmer Hess	Eric, Pa., 1949
Thomas A. McGoldrick	Brooklyn, 1949
James R. McVay, Chairman	
	Kansas City, Mo., 1950
J. D. Hamer	Phoenix, Ariz., 1950
H. B. Mulholland	Charlottesville, Va., 1951
Joseph D. McCarthy	Omaha, 1951
Edward L. Bortz	Philadelphia
R. L. Sensenich	South Bend, Ind.

Walter B. Martin	Norfolk, Va.
George F. Lull	Chicago
Thomas A. Hendricks, Secretary	Chicago

COUNCIL ON PHARMACY AND CHEMISTRY

(Standing Committee of Board of Trustees)

James P. Leake	Washington, D. C., 1949
David P. Barr	New York, 1949
W. Barry Wood Jr.	St. Louis, 1949
Morris Fishbein	Chicago, 1950
G. W. McCoy	New Orleans, 1950
Perrin H. Long	Baltimore, 1950
Elmer M. Nelson	Washington, D. C., 1950
Torald Sollmann, Chairman	Cleveland, 1951
Isaac Starr	Philadelphia, 1951
Robert F. Loeb	New York, 1951
E. M. K. Geiling	Chicago, 1952
Paul R. Cannon	Chicago, 1952
S. W. Clausen	Rochester, N. Y., 1952
E. D. Churchill	Boston, 1953
Joseph Stokes Jr.	Philadelphia, 1953
C. Guy Lane	Boston, 1953
R. T. Stormont	Washington, D. C., 1953
Austin E. Smith, Secretary	Chicago

COUNCIL ON PHYSICAL MEDICINE

(Standing Committee of Board of Trustees)

H. B. Williams	New York, 1949
Frank H. Krusen	Rochester, Minn., 1949
Anthony C. Cipollaro	New York, 1950
M. A. Bowie	Bryn Mawr, Pa., 1950
George M. Piersol	Philadelphia, 1950
W. E. Garrey	Nashville, Tenn., 1951
W. W. Coblenz	Washington, D. C., 1951
John S. Coulter, Chairman	Chicago, 1951
Derrick Vail	Chicago, 1951
W. E. Grove	Milwaukee, 1951
A. C. Ivy	Chicago, 1952
Frank R. Ober	Boston, 1952
Frank D. Dickson	Kansas City, Mo., 1952
Morris Fishbein, ex officio	Chicago
Howard A. Carter, Secretary	Chicago

COUNCIL ON FOODS AND NUTRITION

(Standing Committee of Board of Trustees)

C. L. Ladd	Washington, D. C., 1949
John H. Youmans	Chicago, 1949
H. C. Stuart	Boston, 1950
Morris Fishbein	Chicago, 1950
R. M. Wilder	Rochester, Minn., 1951
Howard B. Lewis	Ann Arbor, Mich., 1951
J. S. McLester, Chairman	Birmingham, Ala., 1951

Philip C. Jeans	Iowa City, 1952
C. A. Elvehjem	Madison, Wis., 1952
William J. Darby	Nashville, Tenn., 1953
George R. Cowgill	New Haven, Conn., 1953
James R. Wilson, Secretary	Chicago

COUNCIL ON INDUSTRIAL HEALTH

(Standing Committee of Board of Trustees)

R. T. Johnstone	Los Angeles, 1949
A. J. Lanza, Chairman	New York, 1949
C. D. Selby	Detroit, 1949
Warren F. Draper	Washington, D. C., 1950
Raymond Hussey	Detroit, 1950
Henry H. Kessler	Newark, N. J., 1950
L. D. Bristol	Harrisburg, Pa., 1951
Paul B. Magnuson	Washington, D. C., 1951
Robert A. Kehoe	Cincinnati, 1951
H. A. Vonachen	Peoria, Ill., 1952
W. A. Sawyer	Rochester, N. Y., 1952
James S. Simmons	Boston, 1952
E. J. McCormick, ex officio	Toledo, Ohio
C. M. Peterson, Secretary	Chicago

COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE

(Standing Committee of Board of Trustees)

W. McK. Craig	Rochester, Minn., 1949
Harold S. Diehl	Minneapolis, 1950
Perrin H. Long	St. Paul, 1950
Richard L. Merling	Columbus, Ohio, 1951
Harold C. Lueth	Omaha, 1951
James C. Sargent, Chairman	Milwaukee, 1952
Stafford Warren	Los Angeles, 1953

AND EX OFFICIO

R. L. Sensenich	South Bend, Ind.
George F. Lull	Chicago

COMMITTEE ON SCIENTIFIC EXHIBIT

Dwight H. Murray, Chairman	Napa, Calif.
James R. Miller	Hartford, Conn.
Gunnar Gundersen	La Crosse, Wis.
Thomas G. Hull, Director	Chicago

ADVISORY COMMITTEE

Howard F. Root	Boston
Paul J. Hanzlik	San Francisco
Ludvig Hektzon	Chicago
Urban Maes	New Orleans
Max M. Peet	Ann Arbor, Mich.
James P. Leake	Washington, D. C.

SECTION OFFICERS 1948-1949

Internal Medicine—Chairman, M. A. Blankenhorn, Cincinnati; Vice Chairman, Priscilla White, Boston; Secretary, Walter L. Palmer, 550 E. 59th Street, Chicago.
Surgery, General and Abdominal—Chairman, William D. McFee, Boston; Vice Chairman, Emile Holman, San Francisco; Secretary, Michael E. DeBakey, 509 Lincoln St., Houston, Texas.

Obstetrics and Gynecology—Chairman, Leroy A. Calkins, Kansas City; Vice Chairman, Herbert E. Schmitz, Chicago; Secretary, Arthur B. Hunt, 102 Second Avenue S.W., Rochester, Minn.

Ophthalmology—Chairman, M. Hayward Post, St. Louis; Vice Chairman, Brittain P. Payne, New York; Secretary, Trygve Gundersen, 101 Bay State Road, Boston.

Rhinology—Chairman, Henry B. Orton, Newark, N. J.; Secretary, Cunningham, New York; Secretary, J. Milton Robb, 1553

odraff L. Crawford, Rockford, Ill.; Vice Chairman, 10nd, Va.; Secretary, Margaret Mary Nicholson, 1801 D. C.

nd Therapeutics—Chairman, Dwight L. Wilbur, San McKeon Cattell, New York; Secretary, Carl V. Moore, 1901

Pathology and Physiology—Chairman, George E. Wakerlin, Chicago; Vice Chairman, Frank W. Konzelmann, Atlantic City; Secretary, Edwin P. Hirsch, 1430 South Michigan Avenue, Chicago.

Nervous and Mental Diseases—Chairman, Francis J. Gerty, Chicago; Vice Chairman, Luman Daniels, Denver; Secretary, Francis M. Forster, 1025 Walnut St., Philadelphia 7.

Dermatology and Syphilology—Chairman, Anthony C. Cipollaro, New York; Vice Chairman, Michael H. Ebert, Chicago; Secretary, Clinton W. Lane, 3720 Washington Blvd., St. Louis.

Preventive and Industrial Medicine and Public Health—Chairman, Oscar A. Sander, Milwaukee; Vice Chairman, C. N. Neupert, Madison, Wis.; Secretary, Rutherford T. Johnstone, 727 W. Seventh Street, Los Angeles.

Urology—Chairman, Hamilton W. McKay, Charlotte, N. C.; Vice Chairman, Norris J. Hechel, Chicago; Secretary, Edward N. Cook, 102 Second Avenue S.W., Rochester, Minn.

Orthopedic Surgery—Chairman, David M. Bosworth, New York; Vice Chairman, Walter P. Blount, Milwaukee; Secretary, Joseph S. Barr, 231 Marlborough Street, Boston.

Gastro-Enterology and Proctology—Chairman, William H. Daniel, Los Angeles; Vice Chairman, Russell S. Boies, Philadelphia; Secretary, Grant H. Laing, 104 South Michigan Avenue, Chicago.

Radiology—Chairman, Harry M. Weber, Rochester, Minn.; Vice Chairman, U. V. Portmann, Cleveland; Secretary, Paul C. Hodges, 950 East 59th Street, Chicago.

Anesthesiology—Chairman, C. Walter Metz, Denver; Vice Chairman, Urban Eversole, Boston; Secretary, John S. Lundy, 102 Second Avenue S.W., Rochester, Minn.

General Practice—Chairman, Winfred B. Harm, Detroit; Vice Chairman, Milton B. Casbolt, Kansas City, Mo.; Secretary, Thomas E. Robinson, 1088 East 21st Street, Salt Lake City.

Diseases of the Chest—Chairman, Shelley U. Marietta, Washington, D. C.; Vice Chairman, Harry C. Warren, San Francisco; Secretary, Jay A. Myers, 91 South 7th Street, Minneapolis.

POSTGRADUATE EDUCATION IN OPHTHALMOLOGY IN THE UNITED STATES

Chairman's Address

EVERETT L. GOAR, M.D.
Houston, Texas

Until a quarter of a century ago it was considered that one could not be much of an ophthalmologist unless one had received at least part of one's education in Europe. This was the popular opinion despite the fact that some of our ablest men had never studied there or at most had spent but brief periods in the various clinics abroad. This belief had considerable basis in fact, for in the latter part of the eighteenth century and throughout the nineteenth the great teachers lived and taught in Europe. In England, Thomas Young, William Mackenzie and Sir William Bowman and on the Continent, Arlt, von Graefe, Helmholtz, Donders and others were opening a new science. Later such titans as Parsons, Priestly Smith, Ernst Fuchs, Axenfeld, LaGrange, Elschnig, Meller and their colleagues added to the sum of knowledge until ophthalmology came into its own as a specialty.

Meanwhile many Americans had gone to Europe to sit at the feet of the masters and had returned to open institutions devoted to the care and study of the eye—to disseminate the knowledge they had acquired and to add to it by scientific and clinical investigation. Near the middle of the nineteenth century Hermann Knapp arrived in New York. He had already attained fame as a teacher in Germany, and his influence as teacher and clinician was soon felt in this country. He contributed immensely to ophthalmology in the United States and left a son and a grandson to carry on the tradition.

The first concerted effort to give a course in the basic sciences related to ophthalmology was by the Graduate School of Medicine of the University of Pennsylvania in 1919, although the University of Colorado gave a very good three months' course which I had the pleasure of taking. This course in Philadelphia has been continued through the years, and it has aided immeasurably in the dissemination of knowledge of ophthalmology in the United States. From this pioneer movement in graduate training similar courses have sprung, until now eight universities are giving postgraduate instruction in these basic sciences.

What is the situation today? I selected this subject for discussion because of the great number of young physicians who would like to enter ophthalmology but can find no place for adequate training. This condition has, of course, been aggravated by the number of veterans who have decided to specialize under the Veteran's Bill of Rights, but aside from this the increasing tendency to leave the field of general medicine would overdemand our training facilities.

It has been estimated that one ophthalmologist should be allotted to 15,000 persons. With the population of the United States at about 140,000,000, it would require about 9,333 ophthalmologists to care for the population. I have not been able to determine accurately how many physicians are practicing ophthalmology wholly or in part, but there are probably about 6,000. There are approximately 2,303 living persons who hold the certificate of the American Board of Ophthalmology and approximately 600 applications pending. Less than half of those practicing ophthalmology have been certificated, but the percentage of certified specialists is increasing each year as the older practitioners are taken out of the picture by death or retirement, and better facilities are furnished for training the younger ones.

If we insist that for one to be proved a competent ophthalmologist he must be certificated by the board—and there are those who disagree with this point of view—let us see what facilities we have for training these young persons, not only to pass the board examination but to produce ophthalmologists who can carry on and develop our specialty. In this discussion I will make no effort to distinguish between the terms graduate and postgraduate education. In recent years the term graduate education has come to mean the longer courses and residencies, while the term postgraduate alludes to the shorter or refresher courses.

Training in ophthalmology must come from one or more of the four following sources: (1) courses in the basic sciences related to ophthalmology, (2) residencies in ophthalmology in a general or special hospital, (3) work in outpatient departments of clinics and (4) association in practice with an experienced ophthalmologist. Probably the best trained men have enjoyed all of these privileges, but like other blessings they come to only the chosen few; most of us have had to get our training where and how we could. This is not the best way, as anyone will admit who has had to dig it out for himself. Therefore, if there is anything that can be done to extend our facilities for graduate and postgraduate training, we should set about it.

According to the information I have been able to obtain, courses in basic sciences related to ophthalmol-

From Baylor University College of Medicine, Houston, Texas.

Read before the Section on Ophthalmology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

ogy, not limited to residents, are given at the following institutions. The number of admissions in each is listed.

Washington University	12
Harvard Medical School	30
University of Illinois	30
New York University College of Medicine	24
Northwestern University	12
Pennsylvania University Graduate School	28
Tulane University	12
Wayne University	20
Ophthalmological Study Council	100

There are, of course, many institutions which give the basic courses to their own residents, and some cooperate with neighboring eye hospitals in that respect. Unfortunately, there are still a very few large eye hospitals where the training is still unorganized and desultory and the residents pick up what information they can get.

According to the Directory Department of the American Medical Association, in September 1947 physicians practicing ophthalmology alone were 1,885, and those practicing ophthalmology and otolaryngology together were 4,070, a ratio of about 1 to 2. It seems certain that in the future this ratio will change, so that within a few years more men will be practicing ophthalmology and fewer otolaryngology. Otolaryngologists say that since the advent of sulfonamide drugs and antibiotics it is difficult to find enough operative work to train men properly. I have even heard otolaryngology referred to as a dying specialty. However, if the otolaryngologists associated with me are a fair example, the specialty is a very lusty corpse. A statistician of the American Medical Association figured that a city of less than 25,000 could not support a physician who practiced ophthalmology alone. That could depend on the number and quality of optometrists in the same city. The fact is that most of the men in the smaller cities practice ophthalmology and otolaryngology, do good work and keep rather busy. Most young men who start to specialize take their training with the idea of being certificated. With the demands made by the Boards of Ophthalmology and Otolaryngology becoming more stringent, few men will spend the necessary time to prepare themselves in both specialties, so that probably the eye, ear, nose and throat specialist is on his way out. This will work a hardship on the smaller communities in the years ahead. I see no workable solution for this except a clinic containing a member of each specialty.

In 1947 there were 630 residencies in ophthalmology and otolaryngology approved by the American Medical Association. Two hundred and forty-one of these are in ophthalmology, 326 in otolaryngology and 73 in both specialties. This does not mean, of course, that 241 ophthalmologists will finish their training each year, for most of the residencies are for at least two years, and some are four years in length. It is safe to say that less than a hundred well trained ophthalmologists are produced each year under our present system. This is not because there is a dearth of candidates, for the applications for basic courses and for residencies exceed the number of places by at least 5 to 1. Several young men who have sought training in ophthalmology have told me that it required not only high grades in medical school, a pleasing personality and a fine record of service, but also a friend with great influence at court to secure such a place. My experience in trying to help a few men have convinced me that this is true.

The situation that confronts us then is that we need more ophthalmologists, we have the material to make them from, but we do not have the places to train them. What can we do about it? That depends largely on whether the profession is willing to go to work on the problem. It is folly to suppose that there are only eight medical schools in the United States capable of having instruction courses not limited to their own residents. Could these courses not be extended to take in others? I am sure that they could. Many general hospitals and small eye hospitals that have not the facilities for basic training would take such men as residents and give them clinical experience. Hospitals that have not had residents in ophthalmology might be induced to find a place for men who had such basic training.

I must pause here a moment to pay tribute to the Ophthalmological Study Council. This was the brain child of three men: Dr. Walter B. Lancaster, Dr. S. Judd Beach and Dr. Theodore L. Terry. These men saw the great need for basic instruction and did something about it. In 1945 they gave this course in Boston to 80 candidates. Because of housing shortage and adverse weather conditions, it was given at St. Petersburg, Fla., in 1946. Seventy-eight students completed this course. Unfortunately, Dr. Terry died before the second course started. Last year the course was given to 112 students in Portland, Maine, and it will be repeated there this year with a limit of a hundred students. The sacrifice of time, energy and money that the men who run this course have freely made has not been generally appreciated—nor have the results of their work. The students who take this course have an examination each week, and their men are so well grounded when they finish that most of them do very well on the basic science part of the board examination. I must mention that while the three men who originated the Ophthalmologic Study Council were members of the American Board of Ophthalmology, the Board did not officially sponsor the council and, aside from the cooperation of individual members who were asked to help in teaching, had nothing whatever to do with conducting it. This statement is made so that no one will assume that because of taking this course, or any other, he is thereby rendered eligible to take the board examination. Every applicant must pass the Committee on Requirements—this rule has been in effect since the board's inception.

In an address before the American Academy of Ophthalmology and Otolaryngology last October, the president, Dr. Alan C. Woods,¹ centered his remarks on the American Board of Ophthalmology. As chairman of the board, I want to take this opportunity to reply. On the whole, Dr. Woods was very kind in his evaluation of the board's work. Two points of criticism which he leveled at the board are certainly debatable. The first was that the requirement of a year's rotating internship was unnecessary and disadvantageous, in that it drew bright young men away from ophthalmology into other specialties that made no such demand. We still have more bright young men that we can train, and I believe that if a

1. Woods, A. C.: Address of President: The Present Policies of the American Board of Ophthalmology and the National Societies in Relation to the Progress of Ophthalmology. *Tr. Am. Acad. Ophth.* 52:5 (Sept.-Oct.) 1947.

candidate is so little interested in ophthalmology that he could not spend a year learning some general medicine, he would not make a very good ophthalmologist. In the first year of eye residency at Johns Hopkins Hospital, the resident is given a certain amount of general medicine, but in most institutions he is not. Personally I believe a man would make a better clinical ophthalmologist if he had three to five years of general medicine, but under present conditions it is impractical to require this. Another criticism was that certain societies require the certificate for admission and that some hospitals and medical schools require it for appointment or promotion to the staff. This is true and to a large extent is desirable. If one admits that the American Board of Ophthalmology has been a potent factor in raising educational standards, then one must agree that there must be some strong incentive for one earnestly to desire the certificate. The certificate has no legal significance, so that it must have a professional one. Certainly, few persons would go to the trouble to prepare themselves for an examination and endure what appears to be a rather nerve-wracking experience to most of the candidates in order to have a piece of paper to hang on the wall that did not mean a great deal. In order to make the certificate worth while and thus raise the standards of postgraduate training, it seemed necessary for the board to request certain organizations to require the certificate as one requisite to admission. While our board was first in the field by many years, it had nothing to do with the formation of the Advisory Board for Medical Specialties. This Advisory Board was sponsored by the Committee on Hospitals and Medical Education of the American Medical Association. While the Board of Ophthalmology is a member of the Advisory Board and sends two members to take part in the discussion at the meetings and while the Ophthalmology Board attempts to cooperate with the other boards, it nevertheless maintains its independence of thought and action, and is not responsible for the action of any other member of the Advisory Board.

Some of the criticisms of the boards alluded to by Dr. Woods as originating with Dr. Chesney do not apply to the American Board of Ophthalmology. We do not require a three year, a two year or even a one year residency in ophthalmology as a prerequisite to examination. We do not require a basic science course. Each applicant's training and experience is evaluated individually, and if the majority of the Committee on Requirements feels that the candidate is qualified he is given the preliminary test. When the Council on Hospitals and Medical Education of the American Medical Association demanded through the Advisory Board that all boards should require three years of institutional training, the American Board of Ophthalmology said that it did not take that training to start a person in the study of ophthalmology and that we had too few institutions in which to train our men. As a consequence, we, with two other boards, were not approved for a certain period. Later it became evident that it was undesirable for all boards to have the same requirements, so that we were reinstated. The American Board of Ophthalmology has been in existence long enough so that everyone who has entered the practice of ophthalmology within the past thirty-two years has known that if he wished to be certificated he had to

make certain preparations for it. Unfortunately, a large number of persons paid no attention during the early years of the board's existence, but now, since the certificate has become increasingly valuable, they want it and are not prepared to take the examination. As for many years certificates have been issued only to those who pass the examination, there are many disappointments. There has been considerable antiboard sentiment created within the profession in recent years by the action of the younger boards in making the requirements so stringent that men established in certain specialties could not meet them without heavier sacrifices than they were willing to make. The fact that certain so-called minor specialties, such as the proctology and the allergy, have not been permitted to form their own boards has led to bitterness. It is evident that hospitals and medical schools should not make certification a requisite to appointment or promotion in a specialty that has not had a board long enough for the staff to have had opportunity to prepare for certification. Time and good judgment on the part of hospital and medical school administrators will solve this problem.

There is one phase of postgraduate training in ophthalmology of which we should be thoroughly ashamed—the training of Negro physicians. That might be said of the education of Negroes in medicine, for there are only two medical colleges devoted to the education of Negroes out of seventy class A schools in the United States, and there are few Negro graduates from the other sixty-eight schools. Considering that 10 per cent of the population is Negro, this is a sorry showing. Only about ten Negro physicians have been certificated by the American Board of Ophthalmology. There are very few places where Negroes are accepted as residents. If the plan for cooperation in medical education proposed at a recent conference of governors from the Southern states matures, there should be a great medical school for Negroes opened, with facilities for postgraduate training.

Having spoken of the situation that exists and having pointed out the fundamental needs in postgraduate medical education in ophthalmology, I must sorrowfully admit that I have no solution to offer. It seems to me, however, that the difficulties are not insuperable. It is impossible that only eight out of seventy of our medical schools are so situated that basic training courses can be given. It is unlikely that cities the size of New York, Philadelphia and Boston, with from two to four medical schools each, could provide a staff for only one course. There are many special and general hospitals in the country that could take on more residents if they were urged. There must be some organization vitally interested in postgraduate education that will persistently try to influence institutions to improve and increase their training facilities. I know of no better group to undertake this task than the American Board of Ophthalmology. While the board has always been interested in this, it has never had a committee that devoted itself wholeheartedly and continuously to this duty. Such a committee has recently been appointed. I believe that within a few years as a result of such a committee's efforts and with the cooperation of the teaching institutions a radical change for the better will occur in postgraduate teaching in ophthalmology.

PREVENTION OF POSTOPERATIVE PULMONARY INFECTIONS

Inhalation of Micropowdered Penicillin and Streptomycin

GEORGE V. TAPLIN, M.D.
Los Angeles

SIDNEY H. COHEN, M.D.
Rochester, N. Y.

and

EARLE B. MAHONEY, M.D.
Rochester, N. Y.

The prevention of pulmonary complications following major abdominal or thoracic surgical intervention is still a matter of deep concern, especially in the northeastern sections of the United States where chronic sinusitis and chronic basilar pulmonary infection are rather common. Pulmonary complications are of two general groups, those associated with pulmonary emboli and those associated with bacterial infection with or without atelectasis. Only the second type is to be considered in this report. The use of chemotherapeutic agents, particularly penicillin and, more recently, streptomycin, has been valuable in reducing the incidence of these complications, but the methods of administration, dosage and ideal duration of treatment are still a matter for some debate.¹ In the series of patients to be presented, stress has been placed on an accurate knowledge of the preoperative bacterial flora of the upper part of the respiratory tract and an attempt has been made to reduce the flora preoperatively by inhalation of appropriate chemotherapeutic agents. In the treatment of acute and chronic bronchopulmonary infections, it has been demonstrated² that organisms sensitive to penicillin or streptomycin may be diminished or greatly

reduced in the respiratory tract by inhalation of aerosols of the appropriate antibiotic. The use of penicillin and streptomycin in the micronized form for inhalation, as described by Taplin and Bryan,³ appears to offer definite advantages over other methods of administration. Figures 1 and 2 show the apparatuses used in this study, which simplify the intrapulmonary administration of penicillin and streptomycin. This study is submitted as a preliminary report. It presents a method for reducing the incidence of postoperative pulmonary infections by inhalation of micronized penicillin or streptomycin.

The pathogenesis of postoperative pulmonary infection is somewhat different from that of the usual lobar pneumonia in that the offending bacteria are usually those seen in the normal flora of the mouth and upper part of the respiratory tract. The incidence of pneumococcal bronchopneumonia corresponds roughly with the incidence of the pneumococcal carrier state in the general population.⁴ Postoperative pneumonia is also frequently due to bacteria which are considered nonpathogenic in the throat but which became pathogenic in the lung when the normal mechanism of clearing the tracheobronchial tree of secretions is disturbed following administration of an anesthetic. It is probable that most cases of postoperative pneumonia begin in this manner from small areas of atelectasis, and prophylactic measures used to prevent the accumulation of bronchial secretions have materially reduced the incidence of this complication. Postanesthetic tracheal suction or bronchoscopic aspiration, hyperventilation, changing the patient's position and encouraging him to cough, early ambulation and other postoperative measures are all methods which tend to prevent the accumulation of secretions and increase the pulmonary ventilation. In addition to these methods, it seems logical to attempt to reduce the existing bacterial flora of the upper part of the respiratory tract by chemotherapy before the operation.

Fig. 1.—Insulator type apparatus used for inhalation of micropowdered penicillin or streptomycin.

Merck & Co., Inc., made a grant-in-aid regarding streptomycin studies and gave supplies of streptomycin preparations.

Parke Davis & Company supplied powdered diphenhydramine hydrochloride ("benadryl hydrochloride") used in these experiments.

Lederle Laboratories, subsidiary of the American Cyanamid Corporation, made grants-in-aid and gave laboratory supplies and penicillin.

With the technical assistance of Carol MacGregor, Juanita Warner, Jack Presburg, M.D., Louis Jensen, Carl Homburger and Edward Roche.

Work was performed in the Departments of Medicine and Surgery, University of Rochester School of Medicine and Dentistry, and Dentistry and Clinics of Strong Memorial Hospital and Rochester Municipal Hospital.

Associate Clinical Professor of Medicine, University of California at Los Angeles (Dr. Taplin), Assistant Resident in Surgery, University of Rochester School of Medicine and Dentistry, Strong Memorial and Rochester Municipal Hospitals, Rochester (Dr. Cohen) and Assistant Professor of Surgery, University of Rochester School of Medicine and Dentistry, Strong Memorial and Rochester Municipal Hospitals, Rochester (Dr. Mahoney).

METHOD AND MATERIALS

The method of study included preoperative cultures of sputum, or of the nasopharynx if sputum was not available, and the bacteria were identified by the usual laboratory methods. Tests of sensitivity to penicillin and streptomycin were performed in order to estimate the probable value of the treatment and as a guide to proper dosage. The test used was admittedly a qualitative one based on the principle described by Fleming⁵: "Penicillin diffuses through agar and inhibits the growth of an organism to a distance proportional to the sensitivity of that organism." In other words, an organism which shows a wide zone of inhibition of growth is relatively sensitive, whereas an organism which shows a small zone of inhibition is relatively resistant. There are many factors in this test which can be further modified and thereby produce a more accurate result; however, for clinical purposes, this simple test has proved satisfactory. As a control group, 195 preoper-

These results indicate the need for greater intrapulmonary penetration by the antibiotic. For example, in patients who showed *Streptococcus viridans* preoperatively, 97 per cent of the organisms were sensitive to penicillin but one-half the patients still had positive cultures postoperatively. A similar series of 51 cases is

TABLE 1.—Micro-Organisms Cultured from Nasopharynx and Sputum Prior to Treatment (195 Cases)

ative cultures were studied in this manner, and the results are tabulated in table 1. It is evident that nearly all the bacteria encountered in this group were sensitive to penicillin and/or streptomycin. A group of 96 patients was not treated by any inhalation therapy, and of the 18.7 per cent presenting postoperative pulmonary infections (table 5) more than 75 per cent had the same bacteria predominating in both preoperative and postoperative cultures.

Forty patients were studied who received penicillin by atomizer (34 patients) or mist type aerosol (6 patients) for two days before and after operation (table 2). This group showed a definite reduction in the number of penicillin-sensitive bacteria present following treatment, but there was not the postoperative response that had been expected. We had believed that penicillin given by ordinary throat spray atomizer would be sufficient to eliminate penicillin-sensitive organisms.

recorded in table 3, but the patients were treated with micropulverized penicillin mixtures rather than the atomized or usual aerosol method. In this series, the *Strep. viridans* were observed to be 100 per cent sensitive preoperatively and only 1 positive culture was observed postoperatively after treatment. The number of cultures positive for *Staphylococcus aureus hemolyticus* was reduced about equally with the atomizer aerosol and with the micronized antibiotic. It is noteworthy that there was an increased number of cultures positive for *Escherichia coli* after this treatment, but there were no postoperative pulmonary infections which were considered a result of this organism.

* Patients received 100,000 units per day (25,000 units for four doses) for two days prior to operation and for two days after operation.

Streptomycin was also used in 40 cases, preoperatively and postoperatively, and the bacteriologic data are recorded in table 4. The streptomycin was administered in the micronized form and according to the dosage schedule outlined (table 4). As in the previous series, *Strep. viridans* was the predominant organism and before treatment was 100 per cent sensitive to streptomycin. *Neisseria catarrhalis* was the second commonest organism seen on culture, and this responded to treat-

5. Fleming, A.: On the Antibacterial Action of Cultures of Penicillin, with Special Reference to Their Use in the Isolation of *B. Influenzae*, Brit. J. Exper. Path. 10: 226-236, 1929.

ment in a higher percentage of cases than *Strep. viridans*, although total numbers are too small to be of significance. It is interesting that in 10 of the 40 patients (25 per cent), the postoperative sputum and/or nasopharyngeal cultures were sterile following the streptomycin therapy.⁶

The results of the prophylactic preoperative and postoperative use of penicillin and streptomycin by inhalation are summarized in table 5. During the period of time in which this study was in progress, it was impossible to obtain a series in which alternate patients were used as controls, but an attempt has been made to compare the series of treated patients with similar series of untreated patients. Fifty consecutive cases in which major abdominal and thoracic operation was done were analyzed, covering a period of February and March 1946. Many of the patients in this series of 50 and in the control series of 96 studied in 1946-1947 received penicillin intramuscularly postoperatively, but none received it by inhalation. All of the control patients were treated with the commonly accepted methods designed to prevent postoperative complications as outlined previously. The postoperative pulmonary complications were divided into three types—bronchitis, bronchopneumonia and definite atelectasis, with or without pneumonia. The patients were followed up closely, and with any suspicion of pulmonary complication repeated roentgenograms were taken.

The gross percentage of pulmonary complications in the periods studied in 1946 and 1947 was 18.0 and 18.7 per cent, respectively, when no inhalation antibiotic therapy was given. The 40 patients receiving penicillin by the atomizer or aerosol method had a 20 per cent incidence of complications, but those receiving the micropulverized form of penicillin had only a 2 per cent incidence. This difference in results may be due in part to poorer pulmonary penetration of the atomized penicillin. However, in 1 of the 6 patients receiving penicillin aerosol postoperative bronchopneumonia devel-

1946, and the incidence of complications was 20 per cent. It should be strongly emphasized that the percentage incidence of postoperative complications does not reflect the severity of the complications. Many complications were mild and did not prolong the postoperative convalescence appreciably, while others were

* Patients received 300,000 units (0.5 Gm.) preoperatively, (300,000 units the evening before and 200,000 units the morning of operation). Postoperatively the patients received 200,000 units per day for two days.

† No growth in 10 out of 40 cases (25 per cent) in postoperative culture

a definite postoperative setback or catastrophe. The true situation cannot be analyzed until more extensive morbidity and mortality data are available. It is obvious that postoperative pulmonary complications in larger series will not be reduced to zero by using micronized streptomycin as they were in this small series of only 40 patients.

The apparent value of the treatment is illustrated by the case reported herein.

REPORT OF A CASE

E. W., an 80 year old white widower, was admitted to Strong Memorial Hospital on Nov. 11, 1946, with a six months' history of fullness in the epigastrium and regurgitation after eating solid foods, which had become progressively severer. At the time of admission, he was capable of retaining liquids only and had sustained decided loss in weight.

Physical Examination.—The patient was a fairly well developed somewhat emaciated 80 year old white man who appeared chronically ill and coughed frequently. The trachea was deviated to the left. The chest was emphysematous, with coarse rales audible over the main portion of the bronchial tree. The heart sounds were faint and regular. There were moderate epigastric tenderness and spasm on the right side, but no masses were palpable. The results of the remainder of the examination were not remarkable.

Laboratory Examination.—The Wassermann reaction was negative. The red blood cell count was 4,670,000, hemoglobin 17 Gm. per hundred cubic centimeters and white blood cells 8,000, with a normal differential count. The urine was normal. The reaction of the stool to guaiac was negative. Tuberculin precipitation was 5.6 Gm. per hundred cubic centimeters; the albumin-globulin ratio was 3.1 to 2.5. Nonprotein nitrogen was 38 mg. per hundred cubic centimeters and alkaline phosphatase 2.3 Bodansky units. Roentgenographic studies and esophagoscopy established the diagnosis of carcinoma of the distal third of the esophagus.

At the time of admission the patient's general physical condition would not permit surgical removal of the esophageal lesion, because of purulent bronchitis, weakness and poor nutrition. His sputum culture contained (1) Friedländer's bacillus (penicillin resistant), (2) nonhemolytic *Hemophilus influenzae* (penicillin resistant), (3) pneumococci (penicillin sensitive), (4) hemolytic streptococci (penicillin sensitive) and (5) *Strep.*

* Prophylaxis consisted of one to two days of therapy before and after operation, with an average of 100,000 units per day.

oped, and the sputum showed *Strep. viridans* and *Staphylococcus albus*. In 3 other aerosol-treated patients postoperative pulmonary infections developed due to penicillin-resistant organisms. Failure in these cases cannot be considered failure due to the aerosol. Forty patients received micronized streptomycin, and there were no postoperative pulmonary complications. Because the micronized form of the drugs was used in the spring and summer months, a similar series of untreated patients was analyzed from the summer of

6. Durant, Sokalchuk, Morris and Brown.²¹ Harris Murray, Paine and Finland.²⁰ Paine, Murray and Finland.²⁰

viridans (penicillin sensitive). Treatment with aerosol penicillin, 25,000 units six times daily, was started on November 18. After several days of aerosol penicillin therapy, the sputum was decidedly decreased in volume and penicillin-sensitive organisms were absent, but Friedländer's bacilli remained. A transthoracic esophageal resection and esophago-gastrostomy were performed on December 5 by one of us (E. B. M.).

On the first postoperative day, the patient was alert and conscious but was seen to be more dyspneic. There were moist rales heard over both lung fields, and bronchoscopy was performed, with removal of a large formed plug of mucus from the right main bronchus, which was cultured. Treatment with aerosol penicillin was started again. Streptomycin was not available. Bronchoscopy was repeated on the second postoperative day, with removal of another mucous plug. Cultures of the aspirated material showed Friedländer's bacillus only on both occasions. Coarse moist rales were heard throughout both lung fields. Roentgenograms showed early bilateral bronchopneumonia and atelectasis on the left side. Streptomycin therapy was started, 0.25 Gm. every six hours intramuscularly and 100 mg. six times daily in 1 cc. isotonic sodium chloride solution by aerosol. On the third postoperative day his lungs were fairly clear and vital signs showed definite improvement. A sputum culture on the fourth day, after two days of streptomycin aerosol therapy, contained no organisms and the lungs were clear. The patient continued to

teria present in the respiratory tract preoperatively. The chemotherapy should obviously be supplemented with all the other prophylactic measures which help to maintain an adequate airway and which clear the bronchi of secretions. The value of postoperative tracheal aspiration with a catheter or with the bronchoscope as a means of preventing or treating atelectasis cannot be overemphasized.

This report indicates a rather high incidence of postoperative complications in the control groups, but the data is influenced by certain factors. Rochester is in an area where an unusually large percentage of the population has chronic sinusitis, and, particularly in the winter and spring, acute infections of the upper part of the respiratory tract are common. The operations included in this series are procedures performed in the upper part of the abdomen and chest, which carry a higher incidence of pulmonary complications than lower abdominal procedures or operations outside body cavities. The patients listed as having bronchitis were not seriously ill from this complication, but were included in the series if they had fever associated with cough and sputum but no pulmonary consolidation. Patients with this type of illness will survive without specific

† Streptomycin—100,000 units three times per day for two days before and after operation.

improve rapidly and was discharged on the fifteenth postoperative day.

Comment.—We feel that if this patient had received both penicillin and streptomycin preoperatively his bronchial tree could have been sterilized and his postoperative pneumonia prevented. When this patient was studied preoperatively, streptomycin was not available in the hospital for prophylactic use. This case demonstrates the clinical value of thorough preoperative and postoperative bacterial study of the sputum.

COMMENT

The results obtained indicate that more emphasis should be placed on the importance of the normal flora of the respiratory tract in the causation of postoperative pulmonary infections. The majority of bacteria commonly seen in the upper part of the respiratory tract are sensitive to penicillin and/or streptomycin, and with preoperative prophylactic chemotherapy their numbers may be reduced or completely eliminated. Chemotherapy should also be continued for several days after operation, until the patient is again able to clear the tracheobronchial tree of secretions, or longer if a specific indication exists. The prophylactic treatment appears to be of specific value if preoperative cultures show bacteria, such as *Strep. viridans*, which may be pathogenic. It is particularly important if preoperative cultures show definite pathogens, such as *Streptococcus hemolyticus*, pneumococci and Friedländer's bacilli. The vast majority of cases of postoperative pneumonia are due to bac-

terial, but they are made extremely uncomfortable by the cough, convalescence may be prolonged and the incidence of abdominal wound disruption is increased. The patients with bronchopneumonia and/or atelectasis were all seriously ill, and in these two groups specific treatment seemed most effective.

It is not the purpose of this report to compare the relative merits of administering penicillin by inhalation in the micronized form with administration by other methods, but the micronized form seems to have some advantage in surgical patients with pulmonary complications. Specimens of the peripheral portion of the lungs have been removed during thoracotomy when the patient has received penicillin prophylactically by this method. Appreciable amounts of penicillin are present, and there is no microscopic evidence that the contact of the penicillin has caused damage to the pulmonary parenchyma. Similar experiments with micronized streptomycin show that it also reaches the periphery of the lungs, although there may be no appreciable amounts present in the blood stream as determined by present methods of assay. These observations indicate that penicillin and/or streptomycin enters the entire bronchial tree, so that the drug is immediately available at the site of infection as well as absorbed in the blood stream in the case of penicillin. Penicillin and streptomycin are also absorbed by the

lymphatic vessels of the lung, since in experiments with dogs therapeutic concentrations were obtained in thoracic chyle, after intratracheal insufflation.

The reaction of the patients to the administration of the micronized form has been in general favorable. The patients are usually grateful that they do not have the repeated needle punctures required by intramuscular or subcutaneous injection. There have been no severe reactions to either penicillin or streptomycin administered by this method, but there have been some untoward effects, most of them minor, and some minor disadvantages to the method. A complete discussion of these features will be published, but it is worth while recording them here in brief.

Analysis of 320 cases in which micropulverized penicillin-dextrose-1 per cent diphenhydramine hydrochloride mixtures, with a mean particle size of 1 micron, were administered by inhalation was made to determine the incidence of local and general allergic reactions. Three patients experienced general urticaria; 1 patient had mild asthma; 1 experienced exacerbation of his epidermophytosis, and 5 per cent noted local allergic sore throat reactions, consisting of redness, swelling and, occasionally, vesicle formation in the mouth, pharynx and tongue. These local reactions subsided in two to five days after discontinuance of treatment, and improvement was speeded by administration of antihistaminics by mouth. Several patients objected to the bitter taste of the penicillin mixtures. Some were troubled with coughing and choking sensations when they first tried the mixture. Nearly all patients were able to learn how to inhale the powdered preparation and avoid coughing after the first dose or two.

The ingredients of the vehicles in the mixtures have now been altered, so that few patients object to the taste of the preparation. Most patients are able to self administer a dose in a period of two to five minutes, using the suction type apparatus, thereby saving considerable nursing time.

It is the opinion of various observers that patients prefer this method of administration to injections or the mist type aerosol apparatus. The method is painless, and the prescribed dose may be self administered with less effort and more rapidly than with the usual mist type aerosol apparatus even when oxygen or some other automatic source of pressure is used.

It is possible that the vehicle dextrose, used in these preparations, acts as an expectorant, since it is hypertonic when it first goes into solution with the bronchial secretions. Several patients who have had chronic bronchitis prior to operation have noted rapid relief of cough, ease of expectoration and reduction in the amount of sputum raised.

This method of prophylactic treatment should be beneficial, particularly in emergency cases in which at the time of operation there is a concurrent acute infection of the respiratory tract. Fifteen patients with postoperative bronchopneumonia have been treated successfully by inhalation of the appropriate antibiotic in the micronized state.

SUMMARY AND CONCLUSIONS

Postoperative pulmonary infections following major abdominal and thoracic procedures occur in 18 to 20 per cent of cases.

Most postoperative pulmonary infections are caused by organisms present in the respiratory tract prior to operation.

Nearly all organisms infecting the respiratory tract are sensitive to either penicillin or streptomycin.

The common pathogens or potential pathogens of the respiratory tract may be temporarily removed or greatly reduced in number before and during the operative and postoperative period by inhalation of relatively small doses of micronized penicillin or streptomycin mixtures. This method of prophylactic treatment has reduced the incidence of postoperative pulmonary complications.

Prophylactic intrapulmonary administration of micronized penicillin and streptomycin mixtures should be especially beneficial in major abdominal emergency conditions with acute concurrent infections of the respiratory tract.

Penicillin and streptomycin assay of peripheral pulmonary tissue obtained from patients undergoing thoracotomy demonstrates penetration of both agents to the terminal bronchial tree.

PREVENTION OF TUBERCULOSIS AMONG STUDENTS OF MEDICINE

HAROLD S. DIEHL, M.D.

RUTH E. BOYNTON, M.D.

SUSANNA GEIST-BLACK, M.D.

and

J. ARTHUR MYERS, M.D.

Minneapolis

After the establishment of the chest clinic at the University of Minnesota Students' Health Service in 1920, an excessive number of patients came from the Schools of Nursing and Medicine. Examinations were then made only of students who requested them.¹ The incidence of primary tuberculosis (tuberculous infection) among students was not known, but it was assumed to be in excess of 90 per cent. In 1928 the tuberculin test was administered to those entering all departments of the university; only about one third reacted.² Subsequently a much higher incidence of clinical tuberculosis was observed among students and recent graduates in medicine throughout the world than in the general populations of the same areas.

SURVEY OF PHYSICIANS GRADUATED FROM UNIVERSITY

In 1941 we reported the results of a survey of the 1,441 physicians graduated at the University of Minnesota from 1919 to 1932, in which a response was obtained from 1,304 (97.4 per cent).³ Among these graduates there were 7.1 per cent who contracted clinical tuberculosis while in school or after graduation. Among those dead from all causes, 26.2 per cent died from tuberculosis. The question arose as to whether this was a higher incidence than among students and graduates in other professional schools. In 1943 we reported on a similar survey of the students and graduates in our School of Law; only 1.3 per cent were found to have contracted the disease while in school or after graduation.⁴

From the Students' Health Service, the School of Public Health and the Department of Medicine, University of Minnesota, Minneapolis.

Because of lack of space this article has been abbreviated in THE JOURNAL by omission of the table. The complete paper will be found in the authors' reprints, which the authors will be pleased to send on request.

TESTING OF ENTERING STUDENTS

In 1928 the tuberculin test was administered to entering students, and in 1929 the test, plus roentgen inspection of the chests of the reactors with a complete examination of those with shadows to determine the causes of lesions, became routine procedure. Non-reactors to tuberculin on entrance were retested with tuberculin annually as long as they did not react. Those who became reactors while in school, as well as those who were reactors on entrance, have had annual roentgen inspections of their chests, with complete examination when indicated.

By the tuberculin test we were able to diagnose primary tuberculosis (tuberculous infection) among entering students. Within eight weeks (rarely earlier than three or more than seven weeks) after human tissues are invaded with tubercle bacilli allergy can be detected by the tuberculin test. A characteristic reaction to tuberculin indicates the presence of primary tuberculous lesions. Therefore we were able to diagnose this disease promptly among any nonreactors on entrance who became infected while in school. Whenever a student contracted primary tuberculosis as indicated by the tuberculin reaction, we studied his contacts and in most cases located the origin of his infection. This enabled us to determine in which hospitals and even in which departments of hospitals the majority of students were infected. The tuberculin test also served as the only accurate criterion of the effectiveness of the tuberculosis control measures.

Among the students entering over a four year period beginning in 1929, with 449 graduating, 35.6 per cent reacted to tuberculin on admission. The percentage of reactors increased to 41 at the end of the third year and to 67.8 at the end of the senior year. Indeed, 50.2 per cent of the nonreactors on entrance reacted on graduation. It was alarming that the incidence of those who became reactors while in school increased in each class. For example, among those who graduated in 1933 and 1936, 57.7 and 77.9 per cent, respectively, reacted on graduation.⁵

Before studies were made on these four classes, our recognition of the problem was based on morbidity and mortality.⁶ Therefore the extreme seriousness of the situation was not perceived until we realized that approximately as many students contracted primary tuberculosis (tuberculous infection) during the brief time they were in medical school as had acquired this disease between birth and matriculation. Our studies have revealed that far more students became infected on tuberculosis services than in general hospitals.⁶

PROGRAM AT UNIVERSITY HOSPITAL

In 1936, a case-finding program was instituted among the personnel and the patients of the University Hospital. This provided for initial and subsequent periodic examinations of all employees, regardless of capacity, and for adequate examination for clinical pulmonary tuberculosis in the patients as soon as possible after they entered the institution, regardless of the cause for admission.⁷ The first examination of the members of

the personnel revealed 3 with contagious disease, and among the patients several cases were found coexisting with other diseases for which they were admitted. Both the employees and the patients in whom contagious tuberculosis was revealed were immediately isolated and treated with strict contagious disease technic so as to protect all of their contacts, including the medical students. In 1938 an identical tuberculosis control program among personnel and patients was instituted at the Minneapolis General Hospital, where many of our students work. Thus, in these two hospitals the likelihood of students becoming infected or reinfected with tubercle bacilli became slight.

ATTITUDE OF STUDENTS

After the routine periodic tuberculin testing program was established, the students themselves manifested considerable concern on seeing in their classes approximately twice as many reactors at the end of the senior year as on admission to the school. In the meantime they had observed several of their classmates who had contracted clinical lesions, and some had become seriously ill. Since all such persons were from the group

Chart 1.—Percentage of tuberculin reactors among medical students on entrance and on graduation.

of tuberculin reactors, the students came to regard such a reaction as an ill omen. Those who did not react to tuberculin were extremely desirous of avoiding the first infection, while those who reacted on admission to the school were equally desirous of preventing reinfections. They saw a significant number of their classmates become reactors to tuberculin soon after returning from residence in a sanatorium. Thus they felt that adequate protection was not afforded them, and therefore many began to object to such a service. Prior to 1936 the sanatorium service had been compulsory, but that year any student who expressed a desire to omit it was permitted to substitute other work in tuberculosis. In 1937 a large percentage of the students made such a substitution, and in the summer of that year residence in the sanatorium was discontinued. Thus a considerable number of the students who graduated in 1937, the majority in 1938 and all in 1939 and thereafter did not have sanatorium service. An arrangement was made for teaching medical students tuberculosis in a general hospital with a chest disease service operated on a strict contagious disease basis.

In discussions concerning tuberculosis control among students of nursing and medicine the phrase, "unavoidable exposure" has been introduced. While some

exposures are unavoidable, we do not believe that they are unavoidable, and therefore the phrase should be abandoned. The diagnosis of contagious tuberculosis has been so simplified and can be made with such promptness that there remains no excuse for the so-called unsuspected case to expose students in either the inpatient or the outpatient departments of our hospitals. Moreover, a satisfactory contagious disease technic has been developed which provides an excellent barrier between students and known cases of tuberculosis in our hospitals and sanatoriums.⁸ The phrase "unavoidable exposure" suggests a fatalistic point of view or a spirit of defeatism. It seemed almost justified in the early years of our work when the problem was so serious, but today we do not know of a single student who became infected while in school from unavoidable exposure.

RESULTS OF CONTROL PROGRAM

The serious efforts to protect our students which began in 1936 promptly proved effective, as indicated by the decrease in tuberculin reactors on graduation during succeeding years from 77.9 per cent in 1936 to 50.4 per cent in 1941 and 37.4 per cent in 1945 (the table and chart 1).

Chart 2.—Percentage of nonreactors to tuberculin among medical students who became reactors during their medical course.

In the table and chart 2 we have presented the percentage of nonreactors to tuberculin on entrance who became reactors during their medical course. In 1936 over 65 per cent of the nonreactors on entrance became reactors while in school. However, when our control program was put into effect there was a rapid decrease of this percentage, reaching 20 in 1941, 7.8 per cent in 1945 and 3.2 per cent in 1947.

The reduction in incidence of primary tuberculosis (tuberculous infection) among our medical students has been accompanied by a decrease in the number of lesions which became large enough to be located by physical examination of the chest, including roentgenographic inspection. This is true among both those who had primary tuberculosis on entrance and those who contracted it while in school. Since fewer students became primarily infected it is probable that a smaller number of reinfections occurred. This leads us to wonder whether exogenous reinfections are not more significant in causing clinical tuberculosis than we had formerly believed.

We regard a characteristic tuberculin reaction (an area of edema or induration of 5 mm. or more in diameter) as diagnostic of the primary type of tuberculosis. In practically all tuberculin reactors dying from any cause primary lesions can be found if post-mortem examinations are done in sufficient detail. However, there is a wide discrepancy between the tuberculin reaction and ability to locate lesions in the living human body by all other phases of the examination, including roentgen inspection of the chest. Only those lesions within the 75 per cent of the lungs visualized on the usual roentgenogram that are large enough and of sufficient density to absorb roentgen rays cast visible shadows. In every person who contracts tuberculosis the disease can be diagnosed by the tuberculin reaction within eight weeks after the bacilli invade the tissues. However, at this time roentgen inspection of the chest rarely reveals any evidence of the disease in more than 5 to 10 per cent of the cases. Later deposition of calcium in primary foci and regional lymph nodes may cast shadows in lesions previously invisible to roentgen rays. Even with this addition it is rarely possible to locate primary lesions of more than 15 to 20 per cent of the persons in whom they exist. Thus the tuberculin reaction constitutes the only method of diagnosing strictly early tuberculosis. At the moment a person becomes a reactor to tuberculin he has tuberculosis just as certainly as the one ill or dead from meningitis or chronic pulmonary disease. The difference is only one of degree. If we had not administered the tuberculin test to our entering medical students but had used all other phases of the examination, we would have obtained an extremely fragmentary picture of the tuberculosis situation among them. If we had not periodically administered tuberculin to those who entered as nonreactors but had used all other phases of the examination, we would now know of few who contracted primary tuberculosis (tuberculous infection) while in school. Thus our work on discovering and controlling the sources of infection and watching for the earliest appearance of reinfection type of lesions among the infected students would have been extremely limited.

There has been considerable controversy with reference to the differences in prevalence of the reinfection type of tuberculosis which develops among students who enter school as reactors to tuberculin and those who become reactors as students. One group contends that those who enter as reactors are immunized, whereas those who become reactors have no immunity and clinical disease is much more prevalent and severe among them. Apparently this controversy hinges on the differences in diagnostic criteria and classification of lesions. Sight is often lost of the fact that every student who becomes a reactor while in school has contracted primary tuberculosis. However, only those in whom demonstrable lesions are found are said to have the disease. Since these students are adults, any roentgen shadow which reveals lesions in their chests has been thought to represent significant reinfection type of tuberculosis. In reality, many of them depict nothing more than primary lesions which are not of clinical significance. Moreover, in some reports persons with nothing more than enlargement of hilus shadows or erythema nodosum have been included in the group said to have contracted clinical tuberculosis.

Sight is also often lost of the fact that students who enter school as reactors have usually already undergone what those who become reactors after entering experience while in school. Primary infiltrates, etc.,

8. Myers, J. A.: Are Nurses and Physicians Protected Against Tuberculosis? *Trained Nurses & Hosp. Rev.* 91:416, 1933. West, C.; Schaller, L., and Myers, J. A.: There Is No Excuse for Tuberculous Infection, *Mod. Hosp.* 59:75, 1942.

have disappeared or been replaced in part by depositions of calcium. Lesions which subsequently appeared among these students are of the reinfection type. Such conditions as fresh primary infiltrates could not be expected to appear among them, and therefore this group presents a smaller number with roentgen shadows.

Much of the controversy, therefore, has resulted from comparing unlike conditions. In 1941 we reported 160 medical students who entered school as tuberculin reactors, and 3.1 per cent contracted reinfection type of lesions while in school or soon after graduation; whereas among 145 who became reactors while in school, in 9.6 per cent demonstrable lesions developed.⁹ This statement might be misinterpreted to mean that more than three times as many students who became reactors while in school contracted tuberculosis as among those who entered as reactors. Actually, this is not true. In fact, of the 9.6 per cent in whom demonstrable lesions were seen, primary complexes and pleurisy accounted for 6.2 per cent; whereas only 3.4 per cent contracted the chronic reinfection type of tuberculosis. Thus, only the 3.4 per cent is comparable with the 3.1 per cent among the students who entered as reactors in whom clinical lesions developed.⁹ Throughout our studies we have been unable to find any significant difference in the development of the chronic reinfection type of tuberculosis among those entering as reactors and those who became reactors while in school.

In the earlier years of our work it was commonplace to diagnose and treat clinical tuberculosis among the medical students. The disease ranged from pleurisy with effusion to progressive pulmonary disease and extrathoracic lesions. Some of the students who were infected or reinfected ultimately died from tuberculosis. However, during the past four years only 1 student contracted a demonstrable lesion while in school. He had tuberculosis on admission to the medical school, as indicated by the tuberculin reaction. He had been sensitive to tuberculin since the age of 14 years. However, by no phase of the periodic examinations, including roentgenographic inspections of the chest, were we able to locate the lesions through March 1946. In December of that year immediately before his graduation a lesion in the upper lobe of the left lung had evolved to such size and density as to cast a definite roentgen shadow. No sputum was produced, but acid-fast bacilli were recovered from gastric washings. This case—the first in four years—created considerable excitement on the campus. The attitude of the faculty and the student body was in sharp contrast to that of a decade before when so many students contracted clinical disease that any new case was almost unnoticed except by those trying to solve the problem. Similar tuberculosis control measures have been applied in a school of nursing with almost identical results.¹⁰

Our tuberculosis control program has had an exceedingly worth while educational value among the students. Between the annual examinations many of the nonreactors test one another or request the test in the clinics where they work or even administer tuberculin to themselves. Through an oversight one of our classes graduated without tuberculin having been administered to the nonreactors in the health service in the senior year. A questionnaire revealed that nearly all of them had been tested elsewhere just before gradu-

ation. In the same class the senior year roentgen inspection of the chest was overlooked. However, all of the reactors had taken the matter in hand and arranged for roentgenograms of their chests. Tuberculosis has become a personal issue among the students. They strive to learn all diagnostic procedures and apply them to patients at every opportunity. On detection of tuberculous lesions they seek for their patients the best therapeutic procedures and arrange for control of contagion.

DIAGNOSIS OF PRECLINICAL CANCER OF THE CERVIX

Cervical Cone Knife: Its Use in Patients with a Positive Vaginal Smear

J. ERNEST AYRE, M.D.
Montreal, Canada

Recent advances in methods of cancer detection by Papanicolaou's¹ vaginal smear and the subsequent development of the "surface-biopsy"² cell-scraping method offer a valuable method of uterine cancer control through early diagnosis. A danger exists, however, that the method might fall into disrepute if hysterectomy were widely practiced on the basis of a cytologic diagnosis alone. Especially could this become true if inexperienced and inadequately trained cytologists were to influence the surgeon's judgment unduly. It therefore seems indicated that every effort to confirm a positive cell diagnosis by biopsy be made before subjecting the patient to radical treatment.

The sensitive "surface biopsy" method, when applied routinely, is bringing to light more and more cases of preclinical cervical cancer. This poses a genuine problem for the surgeon or gynecologist in attempting to confirm the cell diagnosis by cervical biopsy. The work of Novak,³ Schiller,⁴ Pund and Auerbach⁵ and others indicates fairly general agreement that the squamous margin of the squamocolumnar junction is the point of origin of the common squamous cervical cancer. Diagnosis by "surface biopsy" cell study adds further confirmation to this concept. Following a cytologic report of positive results with the "surface biopsy" method and in the absence of a focal lesion clinically, it becomes difficult to decide in which part of the squamocolumnar junction a minute lesion is developing. Frequently the first and the second biopsy may have negative results, and even serial sections may be required to confirm the cell diagnosis of cancer. A danger rests in the possibility that a negative result of biopsy, with no further investigation, may lead to fatal delay, permitting the cancer to develop into a clinical and inoperable cancer before treatment is instituted. On the other hand, it is almost equally important to prevent needless major operation. It is, therefore, of importance that an efficient method of obtaining a true evaluation of growth in the cervix by adequate biopsies be found.

No problem exists in the confirmation by biopsy of the clinically evident carcinoma. Indeed, in the past this has been the stage when most patients with cervical cancers have reached the operating table, often too late

for cure. The preclinical cancer presents a different problem. The sensitivity of the "surface biopsy" cell-scraping in cancer detection places in the surgeon's hands many early cancerous conditions in which the lesion is microscopic in size. In approaching the problem of confirmation by biopsy in such a case, the following factors must be borne in mind:

1. The squamous cancer develops at some point in the squamous margin immediately adjacent to the glandular cervical epithelium. The cancer is, therefore, on the most exposed part of the cervix, and trauma, even a light sponging of the cervix before biopsy, may wipe off enough of the tiny growth so that the pathologic evidence may be lost without the entire growth's being removed.

2. The usual unavoidable trauma, such as cervical dilatation, may macerate the cervix at the junctional region, causing loss of the friable neoplastic tissue, thus altering the course of treatment.

3. In the absence of a focal lesion, visually demonstrable, it may be impossible to decide which lip and, indeed, which segment to select for biopsy.

4. After the biopsy specimen is taken, special care of the sample should be taken to prevent the friable surface cells of the lesion from breaking away and being lost.

In order to give a true evaluation of tissue in this early stage, it is advisable to excise the entire squamocolumnar junction before it is subjected to trauma of

Fig. 1.—Ayre's surgical cone knife (Clay-Adams Company, Inc., 44 East Twenty-Third Street, N. Y.)

any kind. In different cervixes, depending largely on parity and the presence of erosions, the squamocolumnar circle may vary from a diameter of 0.5 cm. to 2 inches (5 cm.). The larger the eroded area, the larger the squamocolumnar circumference. Electrocoagulation is a good method of prophylactic therapy and of obtaining a biopsy specimen, provided that the anatomic structure of the squamocolumnar junction is just right. However, the large percentage of cases in which there is an enlarged and irregular squamocolumnar margin render it unsuitable for biopsy purposes, because a portion of the squamous margin may be missed or because a portion of it may be destroyed by the heat, and the tissue interpretation may, therefore, be erroneous.

In an effort to evolve a nontraumatic surgical instrument to remove the entire squamocolumnar circle of tissue, the surgical cone knife (fig. 1) was developed. Proper application of this instrument permits the excision of the entire squamous margin of the junctional region without necessitating a cervical amputation or a hysterectomy. Multiple or serial sectioning of this ring of tissue enables a precise and accurate diagnosis of squamous cancer in the cervix.

INSTRUCTIONS FOR USE OF THE CONE KNIFE

The narrow blade of the cone knife possesses a dual cutting edge, which renders it highly adaptable to controlled excision of selected tissues. The cervix should be adequately exposed and held in position by anterior and posterior tenacula; then, preceding any surgical dilata-

tion or other trauma to the junctional region, the blade is inserted into the tissues $\frac{1}{4}$ inch (0.64 cm.) outside the squamous margin of the squamocolumnar junction, with the blade directed toward the cervical canal. Light pressure on the blade causes the point to penetrate the tissues, the point of the knife on reaching the center of the circle becomes visible in the cervical canal (fig. 2). The blade is then gently maneuvered through the entire circle, care being taken that the blade be guided around the cervix at a constant distance from the squamous margin, regardless of possible irregularity or asymmetry of its circumference. This permits excision of the entire squamous margin with a fairly superficial quantity of the subepithelial tissue and a small collar of the glandular endocervical epithelium. Following the removal of this collar of tissue, which gives the entire circle of the squamous margin for multiple biopsy, the tissue is laid out in a single strip, and in some cases it may be advisable to embed it in the paraffin before permitting any further tissue sectioning. After the circular biopsy specimen is obtained, the usual surgical management follows. Moderate bleeding may, and usually does, occur following the excision. An excellent method of both controlling the bleeding and providing addi-

Fig. 2.—Diagrammatic representation of uterine cervix with cone knife in operation: (1) Eroded type, showing large squamocolumnar circumference (B). (2) Normal-appearing type, showing small squamocolumnar circumference near cervical os. A, endocervical glandular epithelium, B, margin of squamous epithelium (squamocolumnar junction) and C, squamous epithelium of cervix. The pointed blade with the dual razor-sharp edges is inserted into the cervix 0.5 cm. distal to the margin of the squamous epithelium, being directed toward the center of the cervical circumference. A circular "ring" of tissue is excised, removing the entire squamocolumnar junctional zone for biopsy. Preclinical squamous cervical cancer will be found, if present, in the clear nonstippled portion of the excised collar of tissue.

tional prophylactic therapy is to follow the surgical conization by electrocoagulation. This removes a second cone of tissue, seals off the lymphatic vessels and at the same time controls points of hemorrhage. On the other hand, a Sturmdorff amputation, or a cervical amputation of whichever type may be selected, may follow the careful excision and preservation of the biopsy material.

COMMENT

To avoid needless radical surgery and treatment and yet to insure adequate protection of the patient against cancer and to preserve the valuable function of cytologic study in cancer detection, the following steps are recommended as a logical sequence to a positive result of a cytologic test:

1. In the presence of a suspicious cervical lesion, a biopsy specimen should be taken from this area and a sample of endometrium obtained.

2. In the presence of a clinically obvious carcinoma of the cervix, a confirmatory biopsy may be made immediately preceding the application or insertion of radium.

3. In the presence of a cervical condition which appears benign, with no suspicious lesion, the procedure is more difficult. This is the type of condition being discovered with great frequency with the routine "surface biopsy" scraping method. The experienced cytologist is usually able to state whether the cancer cells are of the usual squamous type or of the less frequent glandular type. If the cells are of the squamous type, the surgical cone knife comes into play and the squamocolumnar circle is excised, giving a "ring biopsy." The second step is electrocoagulation. A sample of endometrium is also obtained for biopsy purposes. If the cells prove to be of glandular type, a curettage of the endometrium and of the cervical canal for biopsy should be made.

4. In large erosions and lacerations, when the squamocolumnar circumference is large and irregular, a Sturmdorff amputation may be indicated initially or following excision of suspected parts of the squamous margin for biopsy.

5. In rare instances when the cytologic evidence is conclusive in the opinion of an experienced cytologist, while results of biopsies are repeatedly negative, a total hysterectomy may be considered if the patient is past her childbearing period.

6. In rare instances, in which results of cytologic study are positive and conclusive, while results of biopsies are negative, and the probability is entertained that a rare tubal or ovarian malignant condition may exist, laparotomy and a possible hysterectomy may be considered.

7. In cases in which fundal carcinoma is suspected on the basis of positively reacting cells of a glandular type, an endometrial biopsy specimen should be obtained for confirmation preceding surgical extirpation or radiation therapy. The treatment, therefore, still rests on the observations of biopsy with one possible exception. A problem is posed: How radical should one be in the treatment of preclinical carcinoma and preinvasive carcinoma of the cervix?

8. In preclinical carcinoma of the cervix, which has not yet reached clinical stage I, it is my contention that a good panhysterectomy may be adequate (except in the rare case in which the lesion has extended up into the canal and may have spread more than is apparent in a lateral direction. The disease in such a case is, of course, beyond the preclinical stage and is actually in stage I or II, demanding treatment accordingly).

9. In the preinvasive cervical cancer (intraepithelial carcinoma or carcinoma in situ), especially during the childbearing period, how radical or how conservative should one be? The cone knife permits serial sectioning to determine proof of actual preinvasiveness. Therefore, in such cases, it is my contention that a Sturmdorff amputation may prove adequate and a total hysterectomy may not be necessary. Such cases, obviously, should be followed up assiduously. The great sensitivity and accuracy of the "surface biopsy" method in following up these cases month by month and year by year should permit an early enough recognition of cells indicating recurrence to give a "second chance," permitting hysterectomy or radiation therapy before dangerous spread occurs.

SUMMARY

The vaginal smear and "surface biopsy" methods offer valuable means of uterine cancer control by early detection.

Indiscriminate hysterectomy on the basis of positive smears without biopsies may cause this important advance in diagnosis of cancer to fall into disrepute.

The cervical cone knife is presented as a practical instrument to permit precision biopsies of the squamocolumnar junction in preclinical cervical cancer, introducing the "ring biopsy."

For the patient with a positive vaginal smear a confirmatory biopsy preceding radical treatment is mandatory to safeguard the future reputation of this valuable advance in uterine cancer control. Various steps in diagnostic treatment are recommended for consideration.

TREATMENT OF STERILITY; INSEMINATION
TIMED BY RAT OVULATION TEST

Report of Thirty-Two Cases

DOUGLAS P. MURPHY, M.D.

and

EDMOND J. FARRIS, Ph.D.

Philadelphia

In a previous communication,¹ we reported on ten conceptions following the use of the rat ovulation test² for the timing of intercourse or insemination.

The present paper also deals with the use of the same test. In this instance, it was employed in order to predict the day for the insemination of a series of 32 women. The observations throw light on the value of the method as an aid in the timing of insemination and also indicate the frequency with which certain infertile women may experience abnormal ovulation reactions.

MATERIALS AND METHODS

Couples who sought assistance, because the wife either had never conceived or, having done so, had failed to do so for a long time thereafter, form the basis for this report.

Each couple was studied primarily from three points of view: (1) sperm status of the husband, (2) patency of the wife's fallopian tubes and (3) character of the wife's ovulation process.

Sperm Status of Husband.—The investigation of each couple was begun by a study of the sperm status of the husband.³

After five days of sexual abstinence, he procured an ejaculate by masturbation. This was expelled into a sterile wide-mouthed bottle. The number of moving sperm cells in the entire ejaculate was determined. This was done by diluting seminal fluid 1:20 with Locke's solution in a pipet for white blood cell counting and examining it under the microscope on a field for red blood cell counting. The number of moving sperm cells per cubic centimeter of the ejaculate was computed. From this figure, it was possible to determine the number in the total ejaculate. The resulting figure was employed to designate the degree of fertility of the husband.⁴

4. Farris, E. J.: The Number of Motile Spermatozoa as an Index of Fertility in Men: A Study of 406 Semen Specimens, to be published.

Patency of Fallopian Tubes.—The degree of patency of the wife's fallopian tubes was established either by tubal insufflation or by hysterosalpinography. The latter method is preferred and was used oftenest.

Ovulation Process.—The probable day of ovulation was detected by the rat test as developed by one of us (E. J. F.).¹ The ovulation reaction of each woman was studied for at least two months and in some cases over a period of many months. The first test was made as a control; during this month insemination was not attempted. It was performed, however, during the first month in which there was a normal or a reasonably satisfactory reaction.

Insemination Technique.—The number of moving sperm cells in the specimen employed for insemination was determined. This was done within an hour and the insemination within two hours of the ejaculation.

The wife was placed on the examining table in the lithotomy-Trendelenburg position. The cervical os was exposed with a bivalve speculum. The seminal fluid was drawn into a 2 cc. tuberculin syringe to which was attached a Bower's antrum cannula. The latter was inserted into the cervix with the expectation of just passing the internal os. In cases in which this was impossible, it was passed to the point where it met resistance. An attempt was made to inject 0.25 cc. of the fluid. Prior to the start of the treatment, the patient was asked to report any sensation in her pelvis which the injection might

Unsuccessful Inseminations

Tubal abnormality	3
Unusual menstrual cycle.....	1
Unexplained	1
Total	47

initiate. The treatment was stopped if she experienced any sensation whatever. As the cannula was being withdrawn, additional fluid was injected along its path.

The blades of the speculum then were closed until they touched the walls of the cervix. A wad of cotton was inserted between the perineum and the handle of the speculum, in order to depress its vaginal end. This maneuver tends to bring the cervix into a position more at right angles to the posterior blade of the speculum, so that the external os faces and is close to the tip of the posterior blade.

The remainder of the seminal fluid was poured down the posterior blade of the speculum, in order to cover the cervical os. The patient remained in the lithotomy-Trendelenburg position, with her cervical os immersed into the seminal fluid for a period of thirty minutes. At the end of this time, the excess semen in the vagina was removed and the patient was discharged.

RESULTS

Inseminations Resulting In Conception.—Fifty-seven inseminations were performed on 32 women. Ten resulted in conception. Eight of the 10 women conceived as a result of the first treatment; the remaining 2 women conceived on their second inseminations.

Inseminations Failing to Result In Conception.—Forty-seven inseminations failed in their objective (table). Thirty-seven (79 per cent) of the 47 failures were charged to either an inadequate number of moving sperm cells or abnormal ovulation. Each of the failures in these two categories was predicted before the insemination was performed.

Five unsuccessful inseminations were carried out either on the day before or the day after that on which ovulation was predicted. These dates were selected in order to test the validity of the assumption that conception requires that insemination be performed on the predicted day of ovulation.

Three failures are attributed to tubal abnormality. These included either narrowing of both tubes or blockage of one of them.

One patient experienced a menstrual cycle of about forty-five days. Insemination was performed on the twenty-eighth day of her cycle. The variable length of the cycle of this woman, together with the abnormal character of her ovulation reaction during the month of insemination, probably accounted for the failure of her treatment. It should be mentioned at this point that each patient had insemination only once each month.

COMMENT

The patients represented a selected group of infertile couples. They had been treated unsuccessfully by others, and there appeared to be no gross reason why they should not have had children.

When the husband has a high sperm count and the wife ovulates normally, it is our custom to recommend intercourse rather than insemination on the day of ovulation as indicated by the rat test. Insemination was chosen in preference to intercourse in this series of cases for a number of reasons. Many of the couples were well advanced in their reproductive age and were eager to have a child as soon as possible. Many of the husbands had sperm counts that were close to or below the fertility level. Many of the wives ovulated abnormally a great part of the time. In view of all of these observations, insemination appeared to offer the best means for securing conception.

The attempt was made to perform insemination in each case during a month when the patient experienced a normal ovulation reaction. In some cases the patient rarely ovulated normally. In such instances, insemination was carried out during a month when the ovulation reaction was not ideal.

In many cases the husband had a low sperm count and the wife's ovulation reaction was unsatisfactory. In such circumstances, it was unlikely that insemination would be successful. It was carried out reluctantly in these cases at the insistence of the couples concerned. In 1 case, for example, insemination was carried out unsuccessfully five times. The husband's sperm count was so low each time that conception was deemed out of the question.

Two facts stand out from the present study. One of these is the high frequency with which conception occurred on the first insemination. The fact that eight out of ten of the conceptions followed the first insemination seemed to speak well for the accuracy of the rat ovulation test as a method for predicting the day when the egg is available for fertilization.

The second point concerns the high incidence of low sperm counts and of abnormal ovulations in the series. In some cases, both played a role in preventing conception.

When one excludes the failures to conceive which were predicted before insemination was undertaken, it would appear that conception was achieved in an extremely high percentage of cases.

BRUCELLOSIS AS A CAUSE OF SACROILIAC ARTHRITIS

A Study of Its Relationship to Rheumatoid Spondylitis

CHARLES LEROY STEINBERG, M.D.
Rochester, N. Y.

Knowledge by physicians of bovine brucellosis as it affects cattle is almost zero. This paucity of knowledge is further complicated by the many accepted fallacies regarding epidemiology, clinical history and control of infection in animals and man. Better dissemination of present day knowledge and more research are needed for a disease which affects 30,000 to 40,000 persons annually in the United States.¹ Physicians generally hold to the idea that infected cattle are destroyed. This is not true. It is economic suicide and a practical impossibility to eradicate bovine brucellosis by slaughter of infected cattle. The generally accepted method of control of this infection in animals by veterinarians is by vaccination of calves and adult cows with strain 19.² The adult pregnant cow should be vaccinated before the fourth month of pregnancy; sanitary procedures and immediate ultimate removal of all animals showing a titer of 1:100 or higher are required for control of this disease. The hygienic habits of cows are such that one infected animal may easily infect an entire herd in a short period of time. Pasteurization of milk and dairy products for human subjects is the only practical method available in view of the confusing and complex picture regarding the ubiquitous existence of this infection in cattle.

The symptoms of brucellosis are so varied that a patient presenting himself or herself is often labeled neurasthenic. One may list any symptom from headache to constipation and be able to fit the picture in with that of chronic brucellosis. The typical wavelike fever is often likened to the initial phase of typhoid. This will be shown in the report in this article of a case of extremely severe brucellosis. Aches and pains in joints are often noticed. Most often no true arthritis accompanies the articular symptoms. The acute phases of brucellosis, whether starting as an acute disease or an acute flare-up of a chronic disease, are similar to that of typhoid except that the entire story is accelerated. The finding of a positive blood culture is conclusive evidence. An agglutinating titer which fluctuates with the disease is also conclusive evidence. A negative agglutinating titer is of no significance. A positive reaction to a cutaneous test for brucellosis should be interpreted in the same manner as a positive tuberculin reaction. The opsonocytophagic test is of questionable value.

Rheumatic (arthralgia) manifestations usually appear in the later subacute stage of the disease. The agglutinating titer is most often elevated in the rheumatic stage, indicating some degree of immunity. On the other hand, hot swollen joints and/or synovitis are a rare complication. Hardy and others³ in a reported

series of cases of undulant fever found arthralgia in 32 per cent and evidence of actual inflammation of joints in less than 2 per cent. Green and Freyberg⁴ concluded that arthralgia is a common symptom of brucellosis but that arthritis is a rare complication. Huddleson⁵ and others classified the rheumatic manifestations as fibrositis, neuritis, synovitis, arthritis and spondylitis. Synovitis usually occurred suddenly, the patient awakening with intensely painful swelling of the joints but absence of local redness. The attack of synovitis lasted from twenty-four to forty-eight hours and usually cleared up within a week. Fluid obtained from these joints was sterile and contained an excess of lymphocytes. The knees, ankles, elbows, wrists and fingers were usually involved. Arthritis was more frequently encountered than synovitis. It usually occurred in the subacute stage and lasted a longer period. It was usually monoarticular, and simu-

Fig. 1.—Roentgenogram taken Dec. 20, 1947, revealing destructive changes in the left sacroiliac joint. There is a loss of definition of the articular margin and a definite oval area of destruction in the bone near the upper part of the joint. This area measures 1 cm. in diameter.

lated tuberculous disease of the hips when it occurred in children. In a series of 100 cases these authors found the following articular involvement: ankles 40 per cent, elbows 10 per cent, hips 25 per cent and sacroiliac joints 4 per cent. They stressed the absence of roentgenographic findings in these cases. The exception to this statement is spondylitis, in which Phalen and others⁶ described destructive lesions of the lumbar vertebrae in 3 cases of spondylitis due to brucellosis. They expressed the belief that spondylitis is probably the most common complicating disorder of the bones and joints referable to undulant fever. These authors agreed that spondylitis as a complication of undulant

fever is most likely to occur in the subacute stage but stated that it may occur as early as three weeks after the onset of symptoms or may be delayed as long as one year. Huddleson⁶ has reported intermittent hydroarthritides as a complication of undulant fever. Palagi⁷

Fig. 2.—Roentgenogram taken at same time as figure 1.

collected 29 cases of spondylitis due to brucellosis from the literature and added 17 of his own cases.

Although many of the authors cited sacroiliac arthritis as occurring as a complication of brucellosis, a careful search of the literature fails to reveal a single report of such a complication. The following report is, therefore, of unusual interest.

Fig. 3.—Showing temperature response of patient M. C. to streptomycin therapy. Four grams of streptomycin was given in divided doses of 0.5 Gm. at three hour intervals.

REPORT OF CASE

M. C., a veterinarian aged 30, was first seen in December 1946. The onset of the present illness began in the summer of 1941. The first symptoms noticed were headache, undue

fatigue and leg aches. He would arise in the morning feeling rather well. A few hours later aches would start in the legs and would be associated with a mild degree of fatigue. Moderate headache would start late in the afternoon and would become intense by night. The leg aches and the degree of fatigue would increase decidedly as the day progressed. The patient himself suspected brucellosis in that he had been working in herds of cows in which the degree of brucellosis infection was as high as 50 per cent. He admitted coming in contact often with infected material from the placenta of aborting cows. The cutaneous test for brucellosis was markedly positive in result. Agglutinating titer was positive, 1:40, on May 10, 1941 and 1:160 on May 12. The symptoms of fatigue, leg aches and headaches continued for two weeks and were unassociated with fever. These symptoms recurred yearly. He consulted an eye physician on several occasions because of the severe headaches. He was informed on each occasion that nothing was wrong with his vision.

The next change in his clinical picture occurred in March 1946, at which time he had pain in the left "hip" on and off

Fig. 4.—Roentgenogram taken Jan. 31, 1947, showing partial healing of the area of destruction previously found in the left sacroiliac area. (This view seems to show ankylosis occurring. However, figure 6 definitely shows that this is not the case.)

for a period of two months. Chills and fever were first noted in April. This febrile phase lasted for eight days. Agglutination for *Brucella abortus* and reactions to cutaneous tests were positive. The symptoms subsided completely after eight days and the patient felt comparatively well until August, at which time he experienced pain in the left "hip," the region of the coccyx and in the right upper quadrant of the abdomen. These symptoms gradually subsided in one month. The next recurrence was in November, at which time severe pain developed in the left sacroiliac area. He was treated with brucella vaccine in dilution of 1:10 subcutaneously. Each injection was followed by a severe reaction of pain in the left sacroiliac area. Whirlpool bath treatment of the lower extremities and heat locally to the left sacroiliac area aggravated the condition. He had to use crutches the latter part of December owing to severe pain in the left sacroiliac area. Examination on December 20 revealed a well developed, well nourished white man

7. Palagi, P.: Le localizzazioni vertebrali nelle febbre ondulate, *Chir. d. org. di movimento* 20: 31, 1934; cited by Phalen, Prickman and Krusen.⁶

whose nude weight was 164½ pounds (74.6 Kg.), height 5 feet 11 inches (180.3 cm.), standard weight 166 pounds (75.3 Kg.), temperature 98.6 F., pulse rate 76 and blood pressure 100 systolic and 70 diastolic. The pupils reacted to light and accommodation. Tonsils have been removed. Roentgenograms of the teeth and gross appearance of the teeth and gums were negative. The posterior part of the pharynx appeared innocent. Examination of the neck, lungs, heart and abdomen revealed no abnormality. Normal motion was present in all joints, but there was extreme tenderness over the left sacroiliac area. The knee jerk on the left side was diminished as compared to the right side. Sensation to heat, cold, pain and touch was normal throughout.

The urine was normal. The red blood cells were 5,710,000, the hemoglobin 16.9 Gm., the white blood cells 9,750. The Schilling differential count revealed stabs 6, segmented cells 60, lymphocytes 20, monocytes 4 and eosinophils 3 per cent. The sedimentation rate was elevated at 25 mm. per hour.

Fig. 5.—Roentgenogram taken at same time as figure 5.

The upper limit of normal by this method is 10 mm. per hour. The blood uric acid was normal at 3.4 mg. per hundred cubic centimeters. Throat culture revealed a rare *Streptococcus viridans* organism. Agglutination for *Brucella abortus* was positive in a titer of 1:320. Five localized areas of healed scars measuring 4 mm. by 4 mm. in diameter were present on both forearms as a result of the vaccine that the patient had received some weeks previously. These indicated the severe nature of reaction that the patient had to the *B. abortus* vaccine. Roentgen examination of the lumbosacral revealed the following (figs. 1 and 2): "Lumbosacral spine: There are five lumbar vertebrae. The alinement of the bones is good, with a normal degree of lumbar lordosis. The intervertebral disks, centra and intervertebral articulations are well visualized and appear normal. Lumbosacral articulation is normal.

"Definite destructive changes are noted in the left sacroiliac joint with loss of definition of the articular margins and a definite oval area of destruction of the bones near the upper border of the joint, which measures 1 cm. in diameter. Widening of the joint space of the left sacroiliac joint is also evident

at its lower margin and there appears to be definite destruction of the articular surfaces in this area. The sacrum and coccyx are otherwise normal. The hip joints are normal.

"Radiographic conclusions: The findings are those of destructive changes in the left sacroiliac joint. This lesion is probably

Fig. 6.—Oblique roentgenogram of left sacroiliac area shows no evidence of ankylosis.

Fig. 7.—Roentgenogram taken at same time as figure 6.

secondary to a bacterial infection and may be consistent with brucellosis involving the joint."

The patient was treated symptomatically and with complete bed rest. The symptoms gradually subsided under this management until Jan. 14, 1947. A shaking chill of one and one-half hours' duration developed, and his temperature rose to 104 F.

on this date. This episode was repeated on Jan. 15, 1947. On the latter date streptomycin was started. He was given 0.5 Gm. of streptomycin intramuscularly every three hours. An initial blood culture was negative, and agglutination for *B. abortus* which was taken this day and reported two days later was positive in dilution of 1:640 titer. The response of the temperature curve and the amount of streptomycin given are shown in graph form in figure 3. A palpable spleen was felt on January 16 and January 17. Rose spots not unlike those of typhoid appeared on the abdomen on the later date. On January 22 the patient reported feeling fine and having practically no pain in the sacroiliac area. On February 12 he began to have a low grade fever (100 to 101 F.) in the afternoon. The temperature returned to normal three days later. It has remained normal ever since. At that time the soreness increased in the left sacroiliac area. This apparent flare-up was precipitated by allowing the patient out of bed. A roentgenogram of the lower part of his back was taken on January 31. A roentgenogram of the lumbosacral portion of the spine, taken Jan. 31, 1947, revealed the following (figs. 4 and 5):

"Lumbosacral spine: The area of destruction previously reported in the lower margin of the left sacroiliac joint and near the upper margin of the sacroiliac joint are again seen as have been previously reported. Both areas of destruction are slightly larger in this examination than on the previous

Laboratory Data on Patient M. C.

Date	Sedimentation Rate	Titer	Blood Culture	Remarks
12-2-1946	25 mm. per hour	1:320		Roentgenogram
1-13-1947	28 mm. per hour	1:640	Negative	Comfortable
1-14-1947				Chill and fever
1-15-1947		1:640	Negative	Streptomycin started
1-22-1947		1:1,280		
1-31-1947	23 mm. per hour	1:1,280		Roentgenogram
2-19-1947	31 mm. per hour	1:640	Negative	
3-12-1947	9 mm. per hour			Comfortable

examination. The intervening positions of the sacroiliac joint show loss of definition and there is a suggestion of bony trabeculae traversing the joint space.

"No other significant abnormality is demonstrable in the lumbosacral spine. Radiographic conclusions: The area of destruction previously reported in the left sacroiliac joint are again evidenced. Since the preceding examination a suggestive area of 'ankylosis' has developed in the midportion of this joint. This would be consistent with partial healing of the pyogenic arthritis of this joint."

Oblique roentgenograms of the sacroiliac joints taken failed to reveal true ankylosis (figs. 6 and 7).

The low grade fever reported February 12 disappeared at the end of three days. Clinical improvement has been constant ever since.

COMMENT

The diagnostic possibilities in this case are: (1) neoplastic disease, (2) sacroiliac arthritis due to *Br. abortus* infection, (3) sacroiliac arthritis due to tuberculosis, and (4) early involvement of the sacroiliac joint as an early sign in rheumatoid spondylitis. Neoplastic disease may be ruled out because of localization of disease to the joints and the duration of the illness and the laboratory findings. This patient was a veterinarian and might be easily infected with bovine tuberculosis. Tuberculin tests and roentgenograms of the lungs were negative in result. Also, the history indicates that the patient first began to have some discomfort in his left sacroiliac joint a year before the present period of

hospitalization. These symptoms lasted a short while, and then a period of ten months elapsed without any symptoms. When the pain recurred, ten months later, it was of a most severe nature. This long interval of freedom of symptoms in the back is against any possible diagnosis of tuberculosis. The factors in favor of a diagnosis of *Br. abortus* infection are overwhelming in spite of the fact that four attempts to obtain a positive blood culture were futile. The patient admitted having delivered calves from aborting cows. And although it is common for veterinarians to wear long gloves in such procedures, it must be remembered that the position of the accoucheur at the tail end of the cow is such that infection may easily enter the gastrointestinal tract. A not too vivid imagination is required to appreciate this point. The rise in agglutinating titer from 1:320 to 1:1,280 for *Br. abortus* is of diagnostic significance. The fact that 0.1 cc. of 1:10 *Br. abortus* vaccine given subcutaneously caused extreme areas of necrosis is of some significance. The opsonocytaphagic test is of such questionable significance that it was not done in this case. The localization of the disease in the sacroiliac joints with subsequent healing as shown by the second roentgenogram taken on Jan. 31, 1947 suggested the possibility that *Br. abortus* might be an etiologic agent in rheumatoid spondylitis. There are several decided differences, however, in the roentgenograms of this case and those of rheumatoid spondylitis. One never sees areas of destruction in the joints as shown in both figures 1 and 3 in this case. Also, there is more production of bone in the sacroiliac area and not destruction of bone in rheumatoid spondylitis. It might be argued that at least in some instances sacroiliac arthritis, which has previously been thought to be a part and parcel of the syndrome of rheumatoid spondylitis, might be due to this organism.

Twenty cases of rheumatoid spondylitis were reviewed by me. Blood cultures, blood agglutination tests and cutaneous tests for brucellosis were performed in 20 cases of typical rheumatoid spondylitis. Blood cultures were negative in all 20 cases. Cutaneous tests for brucellosis were negative in 20 cases. The agglutinating titer for *Br. abortus* was weakly positive in 2 cases. One patient, aged 27, gave a seventeen year history of *Br. abortus* infection. The agglutinating titer was positive in 1:20 titer. Cutaneous tests and blood cultures were negative in result. Roentgen examination of the lumbosacral area of this patient showed blurring of the sacroiliac joints with production of bone on either side of the joints. The findings were considered to be typical of early rheumatoid spondylitis. No involvement was found in the spine. Another patient, aged 32, was given a diagnosis of rheumatoid spondylitis. He showed typical changes in the sacroiliac joints and had lost his lumbar curve. This person's reactions to cutaneous tests and blood cultures were negative for *Br. abortus*. He gave a positive agglutinating titer in a serum of 1:20. One month later this was repeated and found to be 1:40. None of the 20 patients showed destructive regions in the sacroiliac area shown by patient M. C. It might be safely concluded that rheumatoid spondylitis is not caused by *Br. abortus* infection. There might be isolated instances in which sacroiliac arthritis is caused by this organism just as in the case reported here.

However, the bone production of the joints, the tendency for the poker back spine, the involvement of the apophysial joints of the entire vertebral column with eventual bone ankylosis and calcification of the surrounding ligaments is not the picture of *Br. abortus* infection.

The initial response to streptomycin appeared encouraging. However, it must be remembered that the patient had a similar episode of chills and fever ten months previously and had no streptomycin. The temperature chart was almost identical. That is, the temperature dropped to normal in a period of approximately three days. In spite of this, it must be emphasized that four days' medication with streptomycin in a person who has had *Br. abortus* infection over such a long period of time is not a fair clinical trial. The reason for stopping the streptomycin in this case was the severe local inflammation in the buttocks produced by the injections. The patient refused to take any more streptomycin. On Feb. 9, 1947 he again began to have a low grade fever (100 to 101 F.) in the afternoon, indicating that the disease was still active. It should be emphasized that the patient felt symptom free while at complete bed rest and at no other time. Dr. E. T. Wentworth, consulting orthopedic surgeon of the Rochester General Hospital, was called into consultation as to whether or not fusion of the sacroiliac joints, fixation of the joint by some mechanical belt or incision and drainage was in order. He supplied a sacroiliac belt and suggested continued complete bed rest. This treatment would seem to be the most efficacious. His objection to fusion was that (a) the joint would fuse spontaneously and (b) the incision might accidentally enter the bone abscess and a chronic drainage sinus result.

SUMMARY AND CONCLUSION

Br. abortus infection can cause sacroiliac arthritis. The initial process is one of destruction of the joints, causing a local abscess and healing by ankylosis of the joint. Sacroiliac arthritis due to brucellosis should be considered in studying early cases of so-called rheumatoid spondylitis in which the pathologic changes observed roentgenographically are centered in the sacroiliac joints. *Brucella abortus* is not a factor in the cause of rheumatoid spondylitis. The treatment of choice in sacroiliac arthritis due to brucellosis is bed rest and a diet high in calories and in vitamins. This conclusion is drawn from the cases of spondylitis reported in the literature and this reported case of sacroiliac arthritis. No conclusive evidence is offered that streptomycin is of value in the treatment of sacroiliac arthritis due to brucellosis. However, it must be admitted that streptomycin was used for an insufficient period of time in the treatment in this case. It is suggested that streptomycin in an equally divided dose of 4 Gm. daily should be used over a long period of time in a manner similar to that in which penicillin is employed in the treatment of subacute bacterial endocarditis. Streptomycin is a much more toxic drug than penicillin. The suggestion that it be used over a longer period of time should be taken with a great deal of caution. Recent studies⁸ suggest that administration of streptomycin and sulfadiazine is the treatment of choice.

COHESIVE BANDAGE FOR CLUBFOOT IN NEWBORN INFANTS

EMIL D. W. HAUSER, M.D.
Chicago

The earlier clubfoot (*talipes equinovarus*) is treated, the better. This has been known for years, but it was impossible to treat newborn infants because of technical difficulties. Orthopedic treatment was delayed until the baby was 3 months old, when correction could be held by means of a plaster of paris cast. A technic that makes immediate treatment possible is desirable. Repeated

Fig. 1.—Deformities associated with *talipes equinovarus* of the left foot. A, congenital pes valgoplanus of the right foot, with anomalies of toes. B, congenital anomalies of fingers (same patient).

manipulation by the parents is not dependable, and repeated manipulation by the physician cannot be carried out frequently enough to be of much value. Manipulation in itself is not sufficient in any case; there must be retention of the correction that is obtained. The size of the foot has made this a problem. The plaster technic is extremely difficult and is generally considered impossible until the infant is 3 months old. Another disadvantage of the cast is that it interferes with development of the foot and leg, resulting in muscle atrophy. Retention of correction by means of adhesive tape is impractical, since the tape irritates the skin. By means of splints, such as the Denis-Browne splint, treatment

8. Keefer, C.: Personal communication to the author.

can be started when the infant is from 1 to 3 months old, and excellent results are claimed for this method of treatment.

With the introduction of the cohesive bandage technic, treatment is possible immediately after birth. The bandage will stick to itself but will not adhere to the

Fig. 2—Components of a clubfoot deformity.

skin, so that it cannot irritate the skin. It permits early correction of each part of the deformity.

The younger the child, the more rapid is the rate of growth. For this reason, the earlier the correction is started, the more the growth factor will be utilized in obtaining correction. At the same time, the structures are softer and the foot is more malleable and more responsive to treatment.

It is generally believed that the deformity occurs as a result of retention of a developmental position in utero. If the normal development is arrested early, the anatomic changes will be severer than if the unfolding process is interfered with in the latter part of uterine life. There is also a true anomalous type of congenital clubfoot, which is often associated with other deformities, such as malformation of the hand or congenital dislocation of the hip (fig. 1). In both types of deformity, the heel is in the varus position, the anterior part of the foot is adducted and supinated and the foot is plantar-flexed in the equinus position. A foot in this position has a cavus deformity (fig. 2). Associated with these structural changes is an imbalance between the power of the muscle groups; the inverters are stronger than the everters.

To obtain a normal foot it is therefore necessary to correct the deformity and to establish normal balance between the muscles. To obtain normal muscle balance the foot must be brought into the opposite direction and used in this position until the everters have normal power. Correction is never complete, no matter how well the foot looks, until the foot can voluntarily be brought into eversion. The term "eversion" as used here means bringing the foot into pronation and abduc-

tion and the heel into the valgus position, and the term "inversion" means a combination of supination and adduction with the heel in the varus position.¹ In every case the foot must be brought into overcorrection. This is essential. Furthermore, the overcorrection should be obtained before weight bearing is started, since weight bearing with overcorrection will tend to correct the foot further, while weight bearing with any deformity present will tend to increase the deformity. For this reason, the earliest possible correction of the deformity and retention of the overcorrected position are most advantageous.

The key to the correction of the clubfoot deformity is full correction of the varus deformity. The varus deformity of the heel is the most difficult part of clubfoot to correct, and the deformity will always recur unless true correction is obtained. The equinus deformity is the most readily corrected, but this should never be accomplished until the other components have been obviated. If the tendo achillis is lengthened first to correct the equinus deformity, the counterforce by which the varus distortion and the supination are corrected is removed and satisfactory conservative treatment is prevented.

The cohesive bandage technic consists, first, in cleansing the foot and leg for at least two minutes with 1:4,000 aqueous solution of benzalkonium chloride. Benzalkonium chloride has the advantage of cleansing the skin and reducing the bacterial count to a minimum without irritation. After the skin is dry, the foot and leg are painted with compound benzoin tincture, with a sterile applicator. When the benzoin tincture has dried, the cohesive bandage is applied. The leg is encircled just

Fig. 3.—Steps in the application of the cohesive bandage.

above the bulge of the gastrocnemius muscle (fig. 3 [1]). The bandage is applied flat, with no wrinkles, and to accomplish this it is held at its full width while being wrapped. A second bandage is applied in the same manner as the first, overlapping the first by half. This is done by the physician, with an assisting nurse

1. Hauser, E. D. W.: *Diseases of the Foot*, Philadelphia, W. B. Saunders Company, 1939.

holding the leg and cutting the bandage with a 6 inch (15 cm.) bandage scissors. This encircling bandage serves as an anchor for the bandage which is to be used for correction of the varus deformity of the heel, since the cohesive bandage will stick to itself but not to the skin.

Fig. 4.—Results of treatment with cohesive bandage. *A*, and *B*, bilateral clubfoot in a patient aged 7 months. *C* and *D*, appearance of the feet after treatment (age 1½ years).

To correct this deformity of the heel, the cohesive bandage is now started from the encircling anchor bands, on the medial side of the leg. The physician brings the anterior part of the foot into abduction, pronation and dorsiflexion, thus forcing the heel into the maximum amount of valgus position that can be obtained. Then the bandage is brought along the medial side of the leg, ankle and foot, around under the heel and up the lateral side of the leg, to be attached to the encircling bands on the lateral side. This stirrup type of bandaging is repeated, overlapping the previous strip by half, and the heel always brought into the valgus position (fig. 3 [2]). Then an encircling bandage is again applied, overlapping by half, down to the ankle (fig. 3 [3]).

Next, the fore part of the foot is corrected. The anterior part of the foot is encircled twice for an anchor bandage, overlapping by half. The anterior part of the foot is then brought into pronation and abduction, and the cohesive bandage is started from the anchor on the dorsum of the foot, on the medial side. It is brought under the foot, and, with the foot pulled into abduction and pronation, the bandage is taken obliquely across the dorsum of the foot and attached to the medial side of the leg above the ankle (fig. 3 [4]). A second strip is applied, overlapping the first by half (fig. 3 [5]). These are reinforced until sufficient strength is obtained to hold the corrected position. Special care is necessary to obtain a flat bandage over the anterior part of the ankle, since the skin in this area becomes redundant with the correction and there is a tendency for creasing. The entire foot and leg are covered with the bandage. The dorsal and plantar surfaces of the toes are included, so that only the very tips of the toes are visible. The entire bandage is then molded, so that everything is smooth, and the foot and leg are thus in a soft smooth well fitted encasement (fig. 3 [6]).

In order to obtain a support that is adequate to hold the foot against the constantly contracting muscles,

it is necessary to have a much stronger bandage. This is accomplished by reinforcement with water-proof adhesive tape. A roll of 2 inch (5 cm.) adhesive tape is applied to the upper part of the leg in the same manner as that described for the cohesive bandage. The entire technic is now repeated with the adhesive tape, the foot again being brought more into the valgus position, with further abduction and pronation as the tape is applied. The entire foot and leg are encircled with sufficient layers of the adhesive tape to counteract the tendency for the foot to resume its original abnormal position (fig. 3 [7]). These cohesive and adhesive bandages are manually molded, and there is smooth and even pressure throughout the entire extremity.

The interval between changes of bandage is variable, depending on the age at which the correction is started and on the severity of the deformity, as well as the distance from which the patient is brought. Usually the newborn infant with clubfoot is seen at the hospital a day or so after birth, and treatment is started at once. The technic for a newborn infant is the same as previously described, with the advantage that, since the child can easily be seen each day at the hospital, the bandage is reinforced daily, with more correction in each treatment. This is continued for a period of a week. Correction is so rapid at this stage that the bandage becomes ill fitting and an entirely new encasement is applied at the end of a week. This is again reinforced daily, and a new bandage is applied the day the mother takes the baby home. The child is then brought to the office two weeks later, when the bandage is again renewed. The treatment is followed through at the office, and the interval is usually two to three weeks, because of the rapid change of the foot and the loosening of the bandage so that it becomes less effective.

Fig. 5.—Results of treatment with cohesive bandage. *A*, severe bilateral clubfoot in a patient aged 2 months. *B* and *C*, appearance of the feet after treatment (age 2 years and 4 months).

Not only must the deformity be corrected, but any tendency to recurrence of the deformity must be prevented, and for this reason the correction is always retained until the child walks. Since the deformity is corrected so rapidly in the early stage, it is sometimes difficult to make the parents understand the need

for continuous retention of the foot in the overcorrected position until walking in the overcorrected position is assured. For this reason it is important to explain the plan of treatment to the parents at the time it is started and to emphasize the necessity for following through, because there must be overcorrection and it must be retained until walking in the overcorrected position is assured.

It is believed that the internal rotation is associated with the adduction of the foot. The early correction of the foot will influence the tibial deformity.

In some cases a tight tendo achillis will not allow full correction of the equinus deformity. Before the child walks and all other corrections are obtained, a subcutaneous tendon lengthening is done. When the child starts to walk, the outer side of the heel and sole is raised. A brace is used to hold the foot in abduction and external rotation.

A review of 70 consecutive cases showed excellent correction with treatment by means of this cohesive bandage technic (figs. 4 and 5). The advantage of early treatment was clearly established. In 6 cases the tendo achillis was lengthened; 3 patients had plantar fasciotomies, and 2 required further correction at 4 years and another at 6 years of age. In 5 the deformities must be considered congenital anomalies. With the exception of these normal results were obtained.

SUMMARY AND CONCLUSIONS

The earlier the clubfoot deformity is treated, the better. The usual type of clubfoot is due to retention of an early position in utero. This can be corrected, so that a normal foot is obtained in each case. Some cases of clubfoot have involved organic changes. Here early and persistent treatment gives the best results. Overcorrection of the position and retention of the overcorrected position until the child walks are necessary. Braces, and occasionally casts, may be needed to assure correct gait.

A new technic with cohesive bandage is described, which permits accurate and early correction of clubfoot. A summary of results in 70 patients treated during a period of six years clearly established the advantages of this type of treatment.

720 North Michigan Avenue.

Treatment of Pernicious Anemia.—The most satisfactory method of treating patients with pernicious anemia, or any type of macrocytic anemia with a megaloblastic bone marrow, is by the intramuscular injection of 1 cc. of refined liver extract, containing 15 units daily for a period of two weeks. At the end of this time I would give 1 cc. (15 units) three times weekly until the red blood cell count is at least 4,500,000 per cubic millimeter and the hemoglobin a minimum of 12 Gm. (83 per cent.) The maintenance dose, in my opinion, is 1 cc. (15 units) every two weeks, although some have stated that the blood may be maintained in a normal condition by giving such a dose once a month. There is one danger which should always be kept in mind. If an inadequate dose of liver extract is employed, the red blood cell count and hemoglobin may fall below normal limits. Although there may be only a slight reduction, nevertheless there is always the possibility that nervous manifestations may develop, or if already present they may progress, sometimes with alarming rapidity. In general, it may be said that when the blood is kept in a normal condition, the nervous changes, if present, may improve greatly, or at least that they will not progress. If they are not present before treatment is started, they will not appear during the course of adequate therapy.—Sturgis, Cyrus C., M.D., *Official Journal of the Interstate Postgraduate Medical Association—Postgraduate Medicine*, June 1948.

Clinical Notes, Suggestions and New Instruments

PARALYSIS OF LEFT VOCAL CORD FOLLOWING STREPTOMYCIN THERAPY

LAWRENCE K. GUNDRUM, M.D.
Los Angeles

The development of sensitivity to streptomycin when used over long periods of time is not uncommon. Many reports¹ of temporary and occasionally permanent injury to both the vestibular and auditory portions of the eighth nerve have been recorded on their terminals. Just why the eighth nerve has been the only one injured is unexplained. It is reasonable to suppose that other nerves might be similarly affected. However, a search of the literature failed to show injury to any other one from the use of streptomycin.

The following case is reported to show a possible effect of streptomycin sensitivity on the recurrent laryngeal nerve.

REPORT OF A CASE

Mrs. W. L., a white woman 33 years of age, was admitted to the hospital Nov. 10, 1947, with complaints of pain in the right flank centered in an area about the size of a quarter, pain being constant, but more noticeable in the recumbent position, and always accompanied with urgency and frequency of urination.

Past history showed the patient to have had no serious illnesses except an attack of arthritis five years previously. She had an unusually large appetite and drank twenty to twenty-five cups of coffee daily.

Physical examination, including observation of the ears, nose, throat, heart and lungs and neurologic examination, showed nothing abnormal except pain and tenderness in right flank, at about the level of the third lumbar vertebra. Roentgen examination showed decided ptosis of the right kidney, with resultant kinking of the ureter in the pelvic region. On November 17 a suspension of the kidney was done. From December 1 to December 8, 11 Gm. of streptomycin and 2,000,000 units of penicillin were given intramuscularly. About December 20 the patient noticed a lump in her throat; she had some difficulty in swallowing liquids. She became progressively worse, and about Jan. 1, 1948, some hoarseness developed. Examination of the ears, nose and throat on January 13 showed complete paralysis of the left vocal cord. Audiometric tests showed a loss of all tones of less than 5 decibels. Responses to tests of the vestibular apparatus were within normal limits. The reaction to an intradermal test for sensitivity to streptomycin was negative. Kolmer, Muzzini and Kahn reactions were negative. Another complete physical examination, including roentgenographic examination of the chest, failed to reveal any pathologic change. The patient was given large doses of vitamin B complex and seen at weekly intervals until February 20, with no apparent change in the laryngeal paralysis.

COMMENT

This case of laryngeal paralysis is presented as one of possible nerve injury which may be due to sensitivity to streptomycin.

1930 Wilshire Boulevard.

From the Departments of Urology and Otolaryngology of the Queen of the Angels Hospital.

Council on Foods and Nutrition

The following report has been accepted by the Council.

JAMES R. WILSON, M.D., *Secretary.*

THE FORTIFICATION OF MILK WITH VITAMINS A AND D

For many years the Council on Foods and Nutrition has approved fortification of milk with vitamin D. The Council has stated the opinion that fortification of milk as a general purpose food with vitamin A is not in the interest of public health. However, no objection is taken to the concurrent presence of vitamin A when the preparation used for fortifying with vitamin D contains vitamin A in natural association.

The Food and Drug Administration in defining a standard of identity for evaporated milk took no exception to the concurrent presence of both vitamins A and D in fortifying agents when both vitamins are derived from natural sources.

Fish liver oil concentrates, sometimes used for fortifying milk with vitamin D, often contain relatively large amounts of vitamin A. Milk fortified with such concentrates has been accepted by the Council, and a statement of vitamin A content has been permitted on the label. However, claims concerning increased nutritive value because of the vitamin A content have not been permitted.

Before the Council can accept claims for milk fortified with vitamin A it seems desirable to have evidence that such fortification is in the interest of public health, even though the procedure is apparently harmless. Such evidence appears to be lacking. Diets that contain appropriate amounts of milk are likely to contain adequate vitamin A. The evidence now available does not warrant a change in the standing decisions of the Council on Foods and Nutrition concerning specific fortification of specific foods to include fortification of milk with vitamin A.

In its acceptance of milk fortified with preparations from natural sources that contain both vitamins A and D, the Council has assumed that the presence of vitamin A is incidental. In those instances in which the vitamin A component is adjusted to supply a specified amount, presumably the amount of vitamin A is not incidental and fortuitous. In any case, the addition of vitamin A does not constitute sufficient reason for acceptance of advertising that suggests special nutritional advantages. The addition of vitamin A to milk, already a good source of this nutrient, may add to the cost of the milk and is without apparent advantage to public health.

ACCEPTED FOODS

The following products have been accepted as conforming to the Rules of the Council.

JAMES R. WILSON, M.D., *Secretary.*

Mead Johnson and Company, Evansville, Ind.

PROTENUM consists of nonfat milk solids, calcium caseinate, dextrose and cocoa.

Analysis (submitted by manufacturer).—Moisture 3%, ash 7%, fat (ether extract) 2%, protein (N $\times$ 6.25) 42%, carbohydrates other than crude fiber (by difference) 46%.

Calories.—3.7 per gram; 105 per ounce.

Vitamins.—No vitamin claims are made, but water soluble vitamins of milk are contained in the product.

Use.—A whole protein supplement for oral use when extra protein or a concentrated source of protein is required in the diet.

Mead Johnson and Company, Evansville, Ind.

LONALAC consists of lactose, milk fat, casein, calcium phosphate monobasic, potassium carbonate, potassium chloride, calcium hydroxide, calcium chloride, calcium carbonate, magnesium oxide, thiamine, nicotinic acid and riboflavin.

Analysis (submitted by manufacturer).—Carbohydrate (by difference) 38%; fat (ether extract) 28%; protein (N $\times$ 6.38) 27%; ash (including sodium 0.02% and potassium 1.4%) 5.5%, and moisture 1.5%.

Calories.—Per gram, 5; per ounce, 145.

Vitamins.—No specific claims for vitamin content are made, and vitamins which are added are designed merely to replace that quantity of vitamins normally present in milk.

Use.—For use in diets of restricted sodium content.

Council on Physical Medicine

The Council on Physical Medicine and the American National Red Cross have adopted the following statement.

HOWARD A. CARTER, *Secretary,*
Council on Physical Medicine.

CARL J. POTTHOFF, M.D.,
The American National Red Cross.

RESUSCITATION

Joint Statement Issued by the Council on Physical Medicine and the American National Red Cross

THE MANUAL PRONE PRESSURE METHOD RECOMMENDED FOR USE BY NONMEDICAL PERSONS

There are many ways of giving artificial respiration. But in asphyxia it is vitally important that artificial respiration be started without a moment's delay. Most victims of asphyxia will die if delay occurs in providing resuscitation while apparatus is being brought to the scene or medical help is being obtained. Accordingly, the general public should be taught a method for giving artificial respiration that can be administered without apparatus of any kind.

Many manual methods of giving artificial respiration have been proposed. The American Red Cross and other organizations have taught the prone pressure method. This method has several important advantages: 1. It requires no apparatus of any kind and therefore can be started immediately. 2. It is easy to administer properly and has been proved effective in countless cases of asphyxia. 3. The victim lies prone; thus there is little danger of occlusion of the respiratory passage by the tongue. The Council on Physical Medicine of the American Medical Association advises that the Red Cross continue to teach the prone pressure method.

INHALATORS AND RESUSCITATORS

An inhalator is an apparatus that delivers to the victim gas, usually oxygen, under low, continuously positive pressure. The resuscitator delivers the gas under either alternating positive pressure or alternating positive and negative pressure. Many apparatus now available can be adjusted to act either as inhalators or resuscitators.

The Council on Physical Medicine recommends that the gas administered by resuscitator or inhalator to asphyxiated victims be oxygen rather than a mixture of oxygen and carbon dioxide.

When the face mask of a resuscitator is in place and the apparatus functions, simultaneous manual artificial respiration is not necessary because the alternate blow or the alternate blow and suck action of the resuscitator ventilates the victim's lungs.

If an inhalator is used on a victim and he is not breathing, simultaneous manual artificial respiration is necessary. If a victim needing oxygen is breathing, the inhalator adjustment should be used; then manual artificial respiration is not necessary.

In earlier years medical workers looked with disfavor on blow and suck machines. The best resuscitators have now been improved to such extent that if properly used they do not damage the lungs and do in some cases secure better ventilation of the lungs than manual artificial respiration does.

SELECTION OF A RESUSCITATOR

It is important that a resuscitator of reliable type be used, and that it be checked at times to assure its proper adjustment. If the positive or negative pressures increase or decrease appreciably, insufficient ventilation of or damage to the victim's lungs may occur. It is highly important that people who operate the resuscitator be adequately trained concerning when and how to use the apparatus.

Any manufacturer of resuscitators may submit his product together with his advertising and directions for use to the Council on Physical Medicine of the American Medical Association for study and acceptance. The Council gives its seal of acceptance if the apparatus is reliable, effective for the uses intended, and free from unnecessary danger, and if the directions are adequate and the advertising ethical. Any organization wishing to purchase a resuscitator can obtain a list of Council-accepted resus-

citators by writing the Secretary, Council on Physical Medicine, American Medical Association, 535 North Dearborn Street, Chicago, Illinois.

THE ROLE OF THE RED CROSS

The Red Cross will continue to teach the manual prone pressure method for administering artificial respiration. It will emphasize to the public that, although at times a resuscitator has value, it is vitally important to start manual artificial respiration immediately and to continue efforts until a resuscitator has actually commenced ventilation of the lungs. If newspaper, magazine and radio articles bring the resuscitator to general public attention, there is great danger that the public will procrastinate in giving manual artificial respiration while awaiting a resuscitator. Therefore, the Red Cross and all publicists should stress the need for manual artificial respiration, and in stories of rescues where both methods are used they should stress the value gained from the manual efforts.

The Red Cross will not guide the selection of resuscitators and inhalators by local rescue squads or teach when and how to operate them. Such advice should come from the Council on Physical Medicine and from local medical committees authorized by the local medical society to act as advisors to rescue squads. Any inquiries to the Red Cross for such information and teaching should be referred by Red Cross officials to the Council and to the Advisory Medical Committee on Rescue Squads of the local medical society.

In the opinion of the Council, operators should possess detailed knowledge of the mechanical construction of resuscitators and inhalators and should have some knowledge of the physiology of respiration. If the apparatus are to be used intelligently the officials of the community should consult the local medical society and request the name of a physician who will assume the responsibility to instruct the operators. It is important to have a responsible person to make periodic inspection of the equipment and to assist in teaching other instructors.

IMPORTANT POINTS TO BEAR IN MIND

1. A nonbreathing person should be given artificial respiration immediately by the most convenient method at hand, which in the great majority of cases is the prone pressure method. Sometimes a few seconds or longer elapse before the victim can be brought into a proper position. If so, the lower part of his chest should be rhythmically compressed and released while he is being brought into position.

2. The air passages must be free from obstruction. The tongue sometimes presses back into the pharynx, shutting off the airway. The first aider should insert two fingers far back into the mouth and press downward and forward on the tongue. Thus the tongue is brought into proper position. If the victim lies prone, the tongue will then remain in this position. If the victim is not prone, it may be necessary to have an assistant hold the tongue in good position with a handkerchief. Fluid or vomitus may also obstruct the passageway somewhat. If the victim is prone, such fluid usually flows out quickly while artificial respiration is given. However, it may be advisable to wipe out the mouth, reaching far back with a handkerchief.

These measures of bringing the tongue forward and of removing other obstruction should be accomplished at once. If only one first aider is present, he should execute these measures between compressions, starting after the first one.

3. If an accepted resuscitator is at hand, it may be substituted for manual artificial respiration with assurance that sufficient ventilation will occur. Manual artificial respiration, however, is all-important while the rescuer awaits a resuscitator. Use of the manual method should continue while the resuscitator is being adjusted, so that the victim's lungs constantly receive air.

4. If a person has not been breathing for five to ten minutes, the chance of survival is slight, even if the most efficient inhalators or resuscitators are used. Nevertheless, an attempt at resuscitation should be made when the slightest chance for recovery exists. Artificial respiration should never be stopped when a pulse or heart beat can be felt. Recovery of normal breathing may be long delayed, especially in cases of electric shock. Most patients recover within about one-half hour, but some have been resuscitated after several hours of artificial respiration.

REPORT OF THE COUNCIL

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, Secretary.

ARMSTRONG X-4 BABY INCUBATOR, MODEL 500 ACCEPTABLE

Manufacturer: The Gordon Armstrong Company, Inc., Bulkeley Building, 1501 Euclid Avenue, Cleveland 15.

The Armstrong X-4 Baby Incubator, Model 500, is a device for housing newborn infants under conditions of controlled temperature, humidity and oxygen concentration.

It consists of a steel-constructed crib provided with a three-ply safety glass lid that gives full length view of the occupant.

It is provided with connections for the inflowing oxygen and with a cable for the current needed to operate the heater. The apparatus operates on alternating current only, but functions on 110, 150 or 220 volt lines by simply changing the two lamps. It draws 156 watts. The firm informed the Council that the apparatus is tested and approved by Underwriters' Laboratories for use with oxygen. The thermometer is graduated in both the Fahrenheit and the Centigrade scales. The crib is mounted on a four-legged stand bearing casters, and is 104 cm. (41 inches) high. The width and length of the crib are 40 and 81 cm. (15¾ and 32 in.) respectively. The whole weighs 30 Kg. (65 pounds); the shipping weight is 44 Kg. (98 pounds).

Armstrong X-4 Baby Incubator, Model 500

When tested under clinical conditions, the apparatus was reported by an investigator for the Council to be well constructed, safe, compact and easy to operate.

The Council on Physical Medicine voted to include the Armstrong X-4 Baby Incubator, Model 500, in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

ASCORBIC ACID (See New and Nonofficial Remedies, 1947, p. 517.

The following dosage form has been accepted:

WARREN-TEED PRODUCTS COMPANY, COLUMBUS, OHIO

Tablets Ascorbic Acid: 25 mg., 50 mg. and 100 mg.

ESTROGENIC SUBSTANCES (WATER SOLUBLE) (See New and Nonofficial Remedies, 1947, p. 346).

The following dosage form has been accepted:

WYETH, INC., PHILADELPHIA

Tablets Conestron: 1.25 mg. and 0.625 mg.

U. S. Trademark Pending.

DIGITOXIN (See New and Nonofficial Remedies, 1947, p. 248).

The following dosage form has been accepted:

R. J. STRASBURGH CO., ROCHESTER, N. Y.

Tablets Digitoxin: 0.1 mg. and 0.2 mg.

DIIDO-OXYQUINOLINE (See New and Nonofficial Remedies, 1947, p. 191).

The following additional dosage form has been accepted:

B. L. LEMKE & Co., NEW YORK, N. Y.

Tablets Yodoxin: 210 mg.

Introduction

This report is the forty-eighth annual compilation of information and statistics on medical education in the United States and Canada by the Council on Medical Education and Hospitals of the American Medical Association.

In addition to the presentation of the customary statistics concerning medical schools, students and graduates, several subjects of current interest are discussed. These include the deferment of medical and premedical students under the Selective Service Act, the financial support of medical schools, the forthcoming survey of medical education, clinical clerkships, the relative interest of medical students in general practice and the practice of a specialty, the objectives of premedical education and the factors which limit enrolments in existing medical schools. There is also presented a summary of the postgraduate and continuation courses that were offered in the United States during the past year.

In previous years the lists of hospitals approved for internships, residencies and fellowships were included in the Educational Number. This year these lists were published in the May 1, 1948 issue of THE JOURNAL. It was felt that the publication of a special Internship and Residency Number in the spring would provide information concerning approved hospitals at the time when it would be most helpful to those seeking appointments for the following year. Hospitals that have been approved for internship or residency training since the publication of the Internship and Residency Number are listed in this issue.

A number of examining boards in the medical specialties have revised their requirements since the 1947 Educational Number was published. A detailed summary of the requirements of the various American boards is therefore presented again this year.

The data published in the Educational Number are obtained from official reports. The Council and THE

JOURNAL express their gratitude and appreciation to the officers of the medical schools, hospitals and other agencies whose cordial and continuing cooperation makes possible each year the compilation and presentation of this body of fundamental information concerning medical education in the United States and Canada.

Selective Service Act of 1948

Under the Selective Service Act of 1948, all men between the ages of 19 and 25 are liable for registration. Certain persons are exempt from service by reason of having served in one of the armed forces for stipulated periods during World War II. The law is rather liberal in its provisions for the deferment of persons who are necessary to the maintenance of the national health, safety or interest, provided that such deferment is based on the individual's status.

The National Headquarters of the Selective Service System has conferred with representatives of the medical schools and has attempted to arrive at a policy whereby a certain number of students in premedical and medical courses will be given consideration for deferment. These policies have not yet been announced. It is expected that they will be published shortly in a directive for the Selective Service System, although they may not be forthcoming until the local boards are completely established. It would appear that as far as medical students who already enrolled are concerned, there need be little concern relative to their deferment so long as they maintain a satisfactory standing in the respective medical schools.

The difficult problem arises with the premedical students. This gave much trouble during World War II and remains the problem of today. There are many colleges and universities in the United States that give premedical training. In these colleges are many men who at some time in their college career arrive at a decision to study medicine, following which they enroll in certain courses and become premedical students.

With the limited number of men between the ages of 19 and 25 who are liable for service, it is obvious that the deferment of all would-be premedical students will be impossible.

It is believed that a policy will be worked out whereby the responsibility for advising the local boards as to the identity of premedical students will be placed on the deans of the medical colleges of the United States. The deans will be required to accept tentatively for admission at a later date into the medical colleges premedical students who have attained their nineteenth birthday and who have had one year in college. The deans will be permitted to forward to the local boards sufficient certificates of tentative acceptance to insure the proper number of students in each freshman class. The number of certificates permitted a school will include a reasonable allowance for attrition. Acceptance by the medical

Medical School Calendars

This 1948 Educational Number presents data for the 1947-1948 academic year. During this year most schools followed conventional schedules with classes beginning in September or October and ending in May or June. The calendars of the schools that present irregular schedules are summarized in table 1.

Only one school, Mississippi, admitted more than one freshman class during this period. The freshman year in all schools except Utah began in either September or October. Utah admitted its freshman class in June. The second freshman class at Mississippi began in February. Tennessee admitted students quarterly.

Three schools in the United States, Louisville, Minnesota and Marquette, whose calendars remained somewhat irregular as a result of the wartime accelerated

† Two classes graduated because of discontinuation of internship requirement for graduation.

college will not be final until the student has finished his premedical course in a manner satisfactory to the medical college. Once a medical school has tentatively accepted a student, it will be expected that the dean will keep himself informed of the student's academic standing in college over the remaining period of his premedical study, which may extend for one to three years, and that he will keep the student's local selective service board advised of his status.

The National Headquarters of the Selective Service System has made it clear that the responsibility for deferment rests by act of Congress on the local boards. Any certificate which a dean may issue and forward to a local board, through National Headquarters of Selective Service, will be a certificate of identity and will set forth the fact that the student is pursuing satisfactorily a premedical or medical course. Should the student fail to continue his course satisfactorily, the dean will be expected to issue a notice of immediate cancellation of the certificate to the local board to whom it is forwarded. Under those circumstances, the failing student would become promptly subject to classification in a class available for military service.

program, graduated two classes during the period covered by the report. In Canada, the University of Alberta discontinued the requirement of an internship for graduation. As a result of this change, Alberta graduated two classes in June 1948, one class on the completion of a year of internship training and the other class on completion of the four year medical school course.

Northwestern, University of Chicago, and Tennessee graduated students quarterly. Alabama and Queen's, which completed conversion from the accelerated program during the past year, had no graduating classes. In addition to the three schools with quarterly graduations and the three schools that graduated two classes, thirteen other medical schools in the United States, as shown in table 1, held graduations earlier than May or June.

The next graduation is scheduled by all but six schools for either May or June 1949. Northwestern, the University of Chicago and Tennessee will graduate students quarterly. Utah, which continues on an accelerated program although admitting only one freshman class a year, will graduate a class in August 1948 and another

in June 1949. Bowman Gray, which is just completing deceleration, will graduate a class in December 1948 but none after that date until June 1950. Ohio State, which has continued to have one class on an accelerated program, will graduate that class in December 1948. It will graduate another class on the conventional schedule in June 1949.

The medical schools of the United States estimate that they will graduate a total of 5,157 students during the year July 1, 1948 to June 30, 1949. This class will probably be the smallest graduating class in several years. Its small size reflects the fact that when the class was admitted during 1945-1946, it was the smallest freshman class since 1940. This class was selected during the last year of the war, when there was no provision for the deferment of premedical students by Selective Service. During that period medical schools were unable to find a sufficient number of qualified students to fill the available places in their freshman classes. The decline in the number of graduates in 1948-1949 will be a temporary one. On the basis of present enrolments, it may be predicted that the graduating class in 1949-1950 will be larger than the one in 1948-1949.

Approved Medical Schools

The seventy medical schools in the United States approved by the Council on Medical Education and Hospitals of the American Medical Association are shown in table 2; the nine Canadian schools in table 3, and the eight approved schools of the basic medical sciences in the United States and Canada in table 4. There have been no changes in these lists since the 1947 Educational Number.

The Hahnemann Medical College in Philadelphia is on probation, as are also the basic science schools of North Dakota and South Dakota.

On April 15, 1948, the Loyola University School of Medicine officially changed its name to the Stritch School of Medicine of Loyola University. The change of name was not accompanied by any change in the organization of the medical school itself or in the relationship of the school to Loyola University.

Tables 2, 3 and 4 list the quantitative premedical requirements effective next year for each school, the enrolment by classes for the academic year 1947-1948 and the total attendance exclusive of students in the required intern year. The number of graduates from July 1, 1947, to June 30, 1948, is also given for each school.

For the Canadian schools enrolments are also given for premedical students in the medical school as well as for students in a fifth medical year and the required intern year.

The name of the dean or executive officer is given for each school. Changes have been made in the executive officers of nine of the eighty-seven medical and basic science schools in the United States and Canada since the publication of the 1947 Educational Number. The following schools have appointed new executive officers: Arkansas, Iowa, Kansas, Creighton, Oklahoma, Pennsylvania, Marquette, Missouri and North Dakota.

Graduates

The last columns of tables 2 and 3 give the number of graduates from each medical school in the United States and Canada respectively from July 1, 1947 to June 30, 1948. During this period there were 5,543 graduates in the United States and 632 in Canada. As already mentioned, three schools in the United States graduated

two classes during this period and one school, Alabama, had no graduating class. In Canada, Alberta graduated two classes, while Queen's had no graduates as a result of deceleration.

The total students and graduates in the United States per academic year since 1905 are reported in table 5. The 5,543 graduates reported for this year are the third largest number reported for any single academic year since 1910. The record 6,389 graduates reported for 1946-1947 included the students graduated during a thirteen month period in which ten schools graduated two classes.

During 1947-1948 no school had as many as 150 graduates. The schools with the largest number of graduates in a single class were Jefferson 148, Illinois 147, Northwestern 143 and Harvard 140. Seven schools graduated fewer than 50 students in one class: Woman's Medical 35, Utah 36, Albany 40, Vermont 40, Syracuse 41, Bowman Gray 48 and Emory 48.

In Canada the most graduates were at Toronto, 129, and the fewest at Alberta, 32, and Dalhousie, 34.

Of the total of 6,175 graduates in the United States and Canada during 1947-1948, 52.1 per cent possessed a baccalaureate degree. The number and percentage of graduates with a baccalaureate degree from each medical school are shown in table 6.

Enrolments 1947-1948

The enrolment figures for the academic year 1947-1948 for the individual schools are given in tables 2, 3 and 4. The total enrolments of classes in the medical and basic science schools in the United States and Canada are recapitulated in table 7. The total enrolment, excluding students taking a required intern year, in the seventy medical and seven basic science schools in the United States was 22,739. This enrolment is 30 less than the enrolment in the regular classes for 1946-1947, although it is 1,161 less than the total enrolment for that year if the extra classes that were in session as carryovers from the accelerated program are included. The enrolment of 22,739 students during 1947-1948, while below the peak enrolments reached during the period when the accelerated program was in force, is 1,212 greater than the average enrolment during the five year period, 1937-1941, immediately preceding the war. In evaluating the enrolments for 1947-1948 consideration must be given to the fact the junior class in 1947-1948 entered medical school during the academic year 1945-1946 as the smallest freshman class in the last seven years. As pointed out earlier in this report, at the time this class was selected, there was no provision for the deferment of premedical students by Selective Service. Medical schools in that year were unable to fill the available places in the freshman class with qualified students. Had this class been at full strength when admitted, the enrolment in the medical schools would now exceed 23,000.

The medical schools of the United States are at present admitting the maximum number of students that their facilities will permit without producing crowding and a resulting lowering of educational standards. Actually a number of schools are accepting more students than they can satisfactorily accommodate.

The medical schools have analyzed the problem that confronts them with respect to increasing their enrolments as follows: Thirty-seven schools state that they could not accept more students unless their facilities for instruction in both the preclinical and clinical departments could be expanded. Of the remaining

thirty-three schools, twenty-nine would have to enlarge their facilities for instruction in the preclinical departments, and four their facilities for clinical instruction.

It should be understood that the expansion of a medical school involves much more than merely securing the use of a certain number of additional square feet of floor space for classrooms. Expansion also

pose a serious problem for schools located in the congested areas of big cities.

The problem of increasing enrolments is further complicated by the shortage of competent teachers that exists as a result of the failure during the war to allow young men to prepare themselves for careers in teaching and research. The effects of this policy will

includes additional space in laboratories and hospitals and increases in equipment and teaching personnel. For the expanded instructional staff, in turn, additional office and laboratory space and technical personnel must be provided. A significant increase in enrolments in most schools would also necessitate enlargement of the administrative offices, library and animal quarters and an increase in the staffs of these departments. Any additional facilities that might be created would have to be satisfactorily integrated from a physical standpoint with existing facilities. This requirement would

handicap the medical schools in their efforts to expand their teaching staffs for several years to come. Consideration must also be given to the fact that for a number of schools the size and location of the community in which the school is situated would make it unlikely that sufficient additional clinical facilities could be developed to permit the training of more students.

In the section of this report on the financial support of medical schools, figures are presented which show that to conduct their present programs, the medical schools must secure from other sources three times

the sum they collect in tuition from students. Therefore, unlike certain other types of training in which the additional tuition collected would offset or more than offset the cost of an expanded program, the expansion of a medical school, if satisfactory standards are maintained, would require a substantial outlay of funds by the medical school.

The situation with respect to increasing enrolments in existing medical schools in the United States may be summarized by stating that no medical school could undertake to increase its entering class beyond present figures without making substantial alterations and additions to its physical plant and without securing additional financial support to meet the increased operating deficit that would result from the expanded program. For certain schools, the lack of available or potential clinical facilities in the community would make expan-

† Includes figures for additional classes.

sion under any circumstances impossible. Finally, it should be recognized that in some schools enrolments already approach the maximum compatible with the efficient conduct of a satisfactory program.

The total enrolment in the Canadian schools, including one basic science school, was 3,100, which is 118 greater than in the preceding session. There were 398 premedical and 84 fifth (not intern) year students in the Canadian schools. These figures are included in the "total" column of table 3, but not in the "total" column of table 7.

There were 447 students in the required intern year in the United States and 230 in Canada. The total number of students in the United States taking a required intern year is shown in table 16 for each of the academic years since 1930-1931.

Five medical schools in the United States had more than 500 students, excluding those in the intern year. Illinois with 634 students had the largest enrolment. Jefferson had 621, Northwestern 520, Tennessee 511 and Harvard 504.

Seven schools in this country had enrolments under 200. Alabama had 132 students, Vermont 153, Wom-

an's Medical 158, Albany 182, Bowman Gray 184 and Syracuse 190.

In Canada, Toronto with 613 students had the largest enrolment. This number does not include 332 stu-

* Includes two classes.

dents in the premedical years. The smallest enrolment in Canada was at Alberta, with 171 students.

The total enrolment in the schools of the basic medical sciences in this country was 491. Mississippi with 112 students and North Carolina with 100 had the largest enrolments.

In table 8, enrolments in the various classes in the medical and basic science schools in the United States are given for each academic session since 1930-1931. During the 1947-1948 session there were 77 fewer freshmen, 183 more sophomores, 613 fewer juniors and 654 fewer seniors than were reported in 1946-1947. It should be pointed out again that the statistics for 1946-1947 included figures for fifteen additional classes in six schools. A more accurate comparison can be made if these additional classes are not included. Such a comparison shows that there were 230 more freshmen, 451 more sophomores, 383 fewer juniors and 328 fewer seniors in 1947-1948 than in the preceding session.

It should be noted that prior to 1942-1943 the totals shown in table 6 are somewhat higher than the sum

TABLE 7.—Total Enrolments by Classes in Medical Schools of the United States and Canada for the 1947-1948 Session

* Includes additional classes.

of the figures for the various classes in a given year. The discrepancy resulted from the inability of certain schools to classify strictly their students into the conventional graded classes.

Veterans in Medical Schools

The percentage of veterans enrolled in the medical schools and schools of the basic medical sciences in the United States increased from 55.6 per cent in the preceding year to 60.9 per cent in 1947-1948. Of the 22,739 students, 13,837 were veterans. Seventy-five of the veterans were women. In table 9 the composition of the student body of the medical schools and schools of the basic medical sciences in this country is recapitulated by classes.

Veterans comprised 73.4 per cent of the freshman class as compared to 62.8 per cent the preceding year. The percentage of veterans for other classes were sophomores 64.8 per cent, juniors 53.6 per cent and seniors 48.6 per cent.

Distributions of Students by Sex

In table 10 the students enrolled in all the medical and basic science schools in the United States and Canada during the academic year 1947-1948 are classified according to sex. Graduates of the medical schools during the period July 1, 1947 to June 30, 1948 are also classified according to sex in the same table.

Table 11 shows the numbers and percentages of women medical students and graduates in the United States since 1905. In 1947-1948 women totaled 2,159 or 9.5 per cent of the medical students in this country. While the total is 24 less than for the preceding year, the percentage of women increased by 0.4 per cent and represents the highest percentage of women medical students ever recorded in the United States. The percentage of women in the freshman class decreased from 11.1 per cent in the preceding year to 7.9 per cent. The actual number declined from 708 to 514.

Four schools had no women medical students: St. Louis, Dartmouth, Jefferson and North Dakota. Georgetown admitted women students for the first time during 1947-1948. St. Louis has reported that it will admit women beginning with the academic year 1948-1949. One school, the Woman's Medical College, had no men students.

During the past four years the number of medical schools in addition to the Woman's Medical College enrolling more than 30 women has increased from seven to twenty-four. From figures presently available it is estimated that about 7 per cent of the entering class in 1948 will be women.

In Canada women numbered 262, or 7.8 per cent of the total enrolment.

Geographic Source of Freshman Students, 1947-1948

The residence of students in the 1947-1948 freshman class of each medical and basic science school in the United States and Canada is shown in table 12. It is recognized that the residence of certain students may be of brief duration, so that their real geographic source may not be revealed by their residence on entering medical school. On the other hand, the birth place of students is probably no better a criterion of geographic origin, since appreciable numbers of people have permanent residence elsewhere than in the states of their birth.

Table 12 reports the residence of 828 freshman students in Canadian schools. This figure differs somewhat from the freshman enrolment figures given in other tables because table 12 employs the figure for the

first class of premedical students at Queen's and Toronto, since these students are already registered in those schools.

In table 13 is shown the number of first year medical students from each state per hundred thousand inhabitants. For the nation as a whole there were 4.3 fresh-

man medical students per hundred thousand inhabitants. The twelve states without medical or basic science schools had an average of 3.3 first year students per hundred thousand of population. Those states with medical or basic science schools had an average of 4.9 students per hundred thousand of population enrolled as freshmen. This is the second successive year in which states with medical schools have sent a significantly larger proportion of their population to medical schools than those states without medical schools. Prior to 1946-1947, statistics showed that states with and states without medical schools sent almost identical proportions of their populations to medical schools.

In 1946-1947 it was reported that 14.8 per cent of the freshman students admitted by state and municipal schools were nonresidents. During the current year only 9.8 per cent of the freshmen enrolled in these schools were out of state students. In the private

schools 51.3 per cent of the freshmen in 1947-1948 were nonresidents, which is almost identical with the figure 51.4 per cent for 1946-1947.

There are indications that several of the states without medical schools are becoming concerned that their residents are not gaining admission to medical schools in the same proportion as those of other states. In certain states the solution to the problem may lie in the development of a medical school within the state. Several of the states in question, however, are not in a position to establish and maintain acceptable medical schools. For these states the solution may lie in their entering into an arrangement with an existing medical school under the terms of which the state will contribute to the support of the medical school if the school will agree to accept a certain number of qualified students each year from that state. Such a program of regional support is not entirely new, but it is being studied with increasing interest by a number of states. It would appear to be the most logical plan for meeting the needs of those states which do not have the resources or clinical facilities necessary for developing satisfactory medical schools of their own.

In table 14 is recapitulated the number of resident students, students from other states, students from United States territories and possessions, Canadian students and foreign students enrolled in the 1947-1948 freshman class in each school in the United States and Canada.

In 1946-1947 six schools did not admit any out of state students. In the two preceding years every medical school in the United States had accepted some out of state students. During 1947-1948, the number of schools that admitted no out of state students increased to nine. They were Alabama, Georgia, Wayne, Mississippi, Missouri, Oklahoma, South Carolina, Texas and West Virginia. Five schools admitted only 1 or 2 nonresidents. Twenty-two schools admitted more nonresident than resident students, and one school admitted an equal number of residents and nonresidents.

* State with no medical or basic science school.

1. Calculations based on one freshman class for each school.

2. 1947 estimate of U. S. Census Bureau.

There were 74 freshman students, 14 fewer than in 1946-1947, from the territories and possessions of the United States. All these students were enrolled in schools in the United States. Attention has been called recently to Puerto Rico's need for additional well trained physicians.¹ It has been suggested that this need can be met if the medical schools in the United States will admit 30 to 50 properly qualified students from Puerto Rico annually. During 1946-1947, 67 students from Puerto Rico were enrolled in the freshman classes of the medical schools in the United States, while in 1947-1948 the number was 57. It is to be hoped that similar numbers of well qualified students from Puerto Rico will continue to find opportunities for training in this country in the years ahead.

Twenty-two students from Canada were enrolled as freshmen in schools in this country. Fifty-eight students from other foreign countries, 4 more than in 1946-1947, were enrolled in the freshman classes in twenty-eight medical schools in the United States.

Of the 828 beginning students in the Canadian schools, 19 came from the United States in 1947-1948. This number is 6 more than in the preceding year. Canadian schools enrolled 15 beginning students from other foreign countries.

Required Internships

The medical schools that require students to serve an internship before they are granted the degree of Doctor of Medicine are shown in table 15. Six schools in the United States and four in Canada have this requirement. During the past year, Alberta discontinued the requirement, while Queen's instituted it for classes entering in September 1947, and subsequently.

During the academic year 1947-1948 there were 447 students from schools in this country and 230 from Canada in the required year of internship training or

research. The number of students from schools in this country in the required intern year is shown for each year since 1930-1931 in table 16.

States requiring the internship for licensure are listed in table 17. There are twenty-three such states. In addition, the District of Columbia, Alaska, Hawaii, the Virgin Islands, the Canal Zone and the homeopathic board of Connecticut require an internship for licensure. Puerto Rico now requires a two year rotating internship.

The licensing boards of the Canal Zone, Delaware, Hawaii, Idaho, Illinois, Iowa, Michigan, New Jersey, North Dakota, Pennsylvania, Rhode Island, Utah, Vermont, Washington and Wisconsin require the internship to be a rotating service.

Five states (Connecticut, Maryland, Missouri, Texas and Virginia) whose laws do not require internship

training withhold the licenses of candidates from schools requiring an internship for the degree of Doctor of Medicine until the internship is completed. In these states the examination may be taken at any time after completion of the medical school course.

Some states in addition to those listed in table 17 require an internship of graduates from schools outside the United States and Canada and of applicants for reciprocity or endorsement.

The hospitals approved for intern training by the Council on Medical Education and Hospitals of the American Medical Association are generally acceptable in those states requiring an internship for licensure.

TABLE 17.—Medical Licensing Boards Requiring a One Year Internship †

Alabama *	Michigan *	Puerto Rico ‡
Alaska *	Montana	Rhode Island *
Canal Zone *	Nevada	South Dakota
Connecticut (Homeo. Board)	New Hampshire	Utah *
Delaware *	New Jersey *	Vermont *
District of Columbia	New Mexico	Virgin Islands

† Some states in addition to those included in this table require the internship for graduates of medical faculties abroad and from reciprocity or endorsement applicants.

* Internship must be a rotating service.

‡ Two year rotating internship required.

The current list of approved internships was published in the May 1, 1948 issue of THE JOURNAL. Additions to this list appear on page 43 of this issue.

Length of the Academic Year

The length of the academic year in the medical schools and schools of the basic medical sciences in the United States shows considerable variation. For the first and second years it varies from 31 to 44 weeks and averages 34.2 weeks and 34.4 weeks respectively. The third year ranges from 31 to 45.5 weeks and averages 34.9 weeks. The range for the fourth year is from 31 to 52 weeks. The average is 35.7 weeks.

Since the year 1939-1940, nineteen schools have increased the length of the first and second years, eighteen the length of the third year, and seventeen the length of the fourth year. During the same period eight schools have shortened the first year, six the second year, and five the third and fourth years. The net effect of these changes has been to increase the average length of the total medical school course, excluding a required intern year, in the United States from 136.4 weeks to 139.2 weeks.

Graduate, Part Time and Special Students

In table 18 are listed for the United States and Canada those students other than regular medical students and students in a required intern year who were pursuing courses in the medical schools in 1947-1948.

During this period 813 physicians were enrolled in thirty-seven medical schools in the United States for work leading to advanced degrees. In Canada 257 physicians were enrolled for similar work in seven schools. Minnesota with 225 reported the largest number of such students. In Canada, McGill had 166 physicians enrolled.

Forty-three medical schools in the United States enrolled a total of 1,090 other graduate students who were working for advanced degrees in the basic medical sciences. The largest number, 200, was at the University of Chicago. In Canada 68 graduate students were enrolled. Forty-one of these were at McGill.

The number of graduate students enrolled in the medical schools is the highest since the beginning of the war. The number is not significantly greater than before the war, however. It would appear therefore that the deficiency of trained teachers and investigators that was allowed to develop during the war is not being made up as rapidly as might be hoped.

In addition to graduate students, there were 478 other nonmedical students taking medical courses in the United States and 60 in Canada.

Thirty-seven medical schools in the United States reported a total of 2,338 physicians enrolled in formal basic science courses in preparation for certification by a specialty board. The highest enrolments in such courses were reported by Wayne and Northwestern, which had 234 and 231 students respectively. There were 100 physicians enrolled in similar courses in four Canadian schools.

Fifty-one medical schools in the United States reported a total enrolment of 13,187 physicians in

is impressive evidence that the educational responsibilities of the medical schools extend beyond the undergraduate student body to another body of students which is approximately three fourths as large. Furthermore this group does not include the interns or all the residents who receive clinical instruction from medical school departments, nor does it include the students in dentistry, nursing, pharmacy and various technical fields who in many schools receive part of their instruction in a medical school.

Premedical Training

The minimum requirement of the Council on Medical Education and Hospitals for admission to approved

refresher or continuation courses. Two Canadian schools reported a total enrolment of 260 students in courses of this type.

One hundred and five part time or special medical students were enrolled in thirty-three medical schools in the United States.

The figures for the various categories of students listed total 18,011 for the medical schools in the United States and 747 for the Canadian schools. It is probable that a few students were reported in more than one category. Even allowing for this possibility, the total

medical schools since 1918 has been two years of college training. In 1938 the Council recommended that at least three years of college training be required of all candidates for admission. With the exception of California the state licensing boards, by statute in the majority of instances, require that an applicant for licensure must present evidence of having completed two years of college. Seventy-five of the eighty-seven schools in the United States and Canada require three or more years of premedical work. Five schools, Georgetown, Johns Hopkins, Tufts, Vanderbilt and

Laval, require a bachelor's degree. Georgetown, however, requires only 90 semester hours of college work from veterans.

Almost all medical schools are now urging that candidates for admission to medical school arrange their college courses so as to acquire as broad an educational background as possible. Traditionally premedical students have concentrated on courses in biology, chemistry and physics in the belief that such concentration will aid them in gaining admission to medical school or that it will enable them to do better work in medical school. For several years the medical schools have been trying without too great success to persuade premedical students that in passing on a candidate for admission they are primarily concerned with the quality of the work that he has done in the sciences and not the quantity. They have also sought to convince the premedical student that experience has shown that he will experience no undue difficulty in his medical school work if he has taken no more than the minimum number of scientific courses required for admission.

The medical schools recognize that, if the physician is to make his full potential contribution to society, he requires a broad cultural background and an understanding of the forces that shape the world in which he practices his profession. Medical schools are therefore urging students to include in their college programs courses in history, literature, sociology, economics, political science, psychology, philosophy and the fine arts.

The cooperation of the premedical advisers in the undergraduate colleges is needed in gaining acceptance of these suggestions. During the past year the Association of American Medical Colleges has prepared and circulated to the colleges a valuable guide for premedical advisers entitled "Handbook for Advisers to Students Planning to Enter Medicine." If this handbook receives the attention to which it is entitled, a general improvement in the pattern of premedical education in this country should result.

The 1948 Freshman Class

The medical schools and schools of the basic medical sciences in the United States estimate that they will enroll 6,407 freshman students during the academic year 1948-1949. By June of this year the schools had selected 5,907 students for admission. This group included 4,028 male veterans (68 per cent), 1,438 other men (25 per cent) and 441 women (7 per cent). Forty-nine of the women are veterans.

These preliminary figures suggest that there will be slightly fewer veterans in the 1948 freshman class than in the 1947 class. It seems likely that this latter class will mark the peak in the admission of veterans of World War II to medical schools. It would also appear that there will be somewhat fewer women than in the last four or five freshman classes.

Financial Support of Medical Schools

The budgets of the medical and basic science schools in the United States for the academic year 1948-1949 total approximately \$51,000,000. This sum represents an increase of \$8,000,000 or 18.6 per cent over the total budgets of the same schools for the year 1947-1948.

The figure \$51,000,000 does not include grants for research or special teaching projects from outside agencies or any significant portion of the cost of operating the teaching hospitals of the country. It does include a total of approximately \$2,900,000 that the medical schools will spend to support certain activities in their

affiliated hospitals. This sum is largely made up of salaries of professional and technical personnel on hospital staffs and the cost of operating special laboratories in affiliated hospitals and clinics. A small portion represents contributions to the operating budgets of hospitals and dispensaries used by the medical school for teaching purposes. It should be pointed out that part of the increase of \$8,000,000 in the budgets reported by the medical schools is accounted for by the fact that some schools included these various expenditures in their affiliated hospitals for the first time in reporting their budgets for 1948-1949.

This year all but fourteen schools supplied figures which included the cost of maintenance of the physical plant and all but four the cost of operating the library. Last year thirty-three schools did not report the cost of plant maintenance, and twenty-six did not include the budgets of their libraries.

Last year's figures included charges for general university administration for eighteen schools. Such a charge constitutes a real part of the cost of medical education, but since the majority of schools do not carry a charge for general university administration, the eighteen schools that do were asked to deduct it so that the figures obtained from each school might be more comparable. This year only three schools indicated that this charge was included in the budgetary figures that they reported. The net result of including

TABLE 19.—*Expenditures per Student by the Medical and Basic Science Schools in the United States, 1948-1949*
Excluding research funds from outside sources

	Number of Schools

Over 5,000.....	2
Total.....	77

the cost of plant maintenance and operation of the library and deducting the charge for general university administration was to increase the total budgets of the medical schools by \$1,000,000.

Not included in the \$51,000,000 that it will cost to operate the medical schools during the coming year are the direct and frequently substantial contributions that many teaching hospitals make to the educational programs of their affiliated schools. These contributions take the form of partial or full support of teaching personnel, research and student laboratories, and the furnishing of classroom space and other accommodations. Neither does the \$51,000,000 include the value of the services contributed by unpaid members of the teaching staffs. In many schools teachers who serve without pay are responsible for a major part of the instruction in the clinical departments.

The schools have estimated that during the academic year 1948-1949 they will receive from outside agencies a total of \$16,630,000 in grants for research and \$3,200,000 in grants for special teaching activities. Last year funds in these categories totaled \$15,400,000 and \$2,600,000 respectively.

The range of expenditures per student that the schools will make during 1948-1949 varies from \$735 to \$9,500. In table 19 the seventy-seven medical and basic science schools in the United States have been

arranged in eight groups according to their anticipated expenditures per student. Grants from outside agencies for teaching and research were excluded in these computations. A comparison of these figures with those for 1947-1948 reveals that for the coming academic year the number of schools spending less than \$1,500 per student has decreased from 34 to 16, and the number spending \$2,000 or more per student has increased from 29 to 39.

Receipts from tuition fees during the coming year will total only \$12,800,000, or 25 per cent of the budgets of the medical schools. In 1947-1948 tuition fees provided approximately \$12,000,000, or 28 per cent of the budgets of the medical schools. Last year it was reported that seventeen schools were unable to match student fees dollar for dollar with funds from non-student sources. The number of schools in this category for 1948-1949 has decreased to seven.

This review of the financial status of the medical schools indicates that the schools have experienced a definite measure of success in securing additional operating funds during the past year. The increase in funds has made it possible for most schools to maintain the quality of their educational programs even in the

presence of inflation. The schools owe much of their success in meeting the problems of inflation to the deep loyalty of their staffs, whose salaries in many cases have not kept pace with the rising cost of living. Only a few schools have indicated that some curtailment of established activities has been necessary for budgetary reasons.

The medical schools, however, are almost unanimous in declaring that if they are to continue to meet the problems of inflation successfully and if they are to undertake new developments important to their fundamental programs of undergraduate medical education, they will require additional operating funds in addition to those currently available. About four fifths of the schools were able to furnish estimates of their needs. On the basis of the figures submitted, it can be estimated that the additional funds needed by all the medical schools amount to about \$15,000,000 annually. This need for additional funds is not all of recent origin. At least one third of the schools have never received adequate financial support, and the correction of long standing deficiencies is one of the important uses for which additional funds are needed.

The medical schools were also asked to estimate the additional funds that they need for capital developments. Five schools indicated that they did not need additional funds. Seventeen schools were unable to furnish estimates. Fifty-five schools supplied estimates which totaled \$197,357,960.

Medical education in this country is at the highest point of its development that has yet been reached. Notable advances are still being made. Substantial improvements have been effected, particularly among a large group of the less wealthy schools, many of which have been able to double, triple, or even quadruple their budgets in the last ten years. However, the problems presented by inflation and the recognition that additional advances in our system of medical education could be made if more funds were available are causing those who are responsible for the conduct of medical education concern as to whether satisfactory progress can be maintained in the future. As a consequence, medical educators have been giving close and urgent study to possible methods by which the basic financial support of the medical schools can be increased. In some quarters it is felt that the solution lies in seeking direct federal subsidies on a large scale. This solution implies such a fundamental change in the philosophy of the support and control of medical education that there is a growing conviction that before such aid is sought, an intensive effort should be made to secure the needed funds from voluntary sources and local units of government. There is good evidence for the belief that the medical schools have not adequately presented their problem to the general public and that, if the public can be informed of the needs of the schools and the reasons for these needs, much more generous support of the medical schools will be forthcoming. The ultimate solution of the problem of adequate support of the medical schools is not yet apparent. It may be predicted that the problem will continue during the coming year to receive the serious and critical attention of all who are concerned with medical education.

Fees

The average tuition fee for an academic year charged by the medical schools in the United States increased only 21 per cent from 1940 to 1947. To help meet rising costs a number of schools found it necessary to raise tuition fees for 1947-1948. The average tuition fee for 1947-1948 was \$480, representing an increase of 4.5 per cent over 1946-1947 and an increase of 27 per cent over 1939-1940. Thirty-two schools have announced increases in tuition charges for the coming year. These increases will raise the average tuition fee for 1948-1949 to \$513, an increase of 7 per cent over the preceding year and an increase of 36 per cent over 1939-1940. While this is a substantial increase, it should be pointed out that it amounts to less than half of the general increase in the cost of living that has occurred during the same period. Attention should also be drawn to the fact brought out in the preceding section that tuition fees will provide only 25 per cent of the cost of operating the medical school during the forthcoming year, and that, despite the increases in tuition, this is a slightly smaller proportion of the total operating costs than was met by student fees in 1947-1948.

A number of medical schools are prepared to give assistance from scholarship and loan funds to individual students who will have difficulty in paying the increased tuition fees.

In table 20 the eighty-seven medical schools and schools of the basic medical sciences in the United States and Canada have been arranged in groups according to tuition fees charged resident students for the sessions 1947-1948 and 1948-1949. The figures are

based on the average tuition fee charged for the complete medical course and include minor charges such as those for matriculation, breakage, diploma and graduation. Thirty-two schools in the United States make an additional charge for nonresidents. These sums vary considerably in amount. The lowest is \$55 and the highest \$400.

Plans of Medical Students for Future Practice

Concern has been expressed in several quarters in recent years that few present day medical students are planning to enter general practice. The results of studies on this point made by certain of the medical schools are, therefore, of interest. Fifteen schools constituting a representative cross section of the medical schools of the country reported that during the past year they sought information from the students in one or more classes concerning their plans with respect to practice.

Polls of nine senior classes were conducted. In four the majority of students planned to enter general practice and in four to specialize. One class was almost evenly divided. The averages for the nine classes were: 48.9 per cent intended to specialize; 41.6 per cent to enter general practice; 9.5 per cent were undecided.

Four junior classes were polled. In two the majority were undecided. A majority of one class favored general practice. The fourth class was equally divided. The averages for the four classes were: 30 per cent intended to specialize; 32 per cent to enter general practice; 38 per cent were undecided.

Polls of five freshman and sophomore classes revealed that in all but one the majority of students were undecided. The averages for the five classes were: 18 per cent planned to specialize; 30 per cent to enter general practice; 52 per cent were undecided.

The overall averages for the eighteen classes included in the study were: 36 per cent planned the specialize; 36 per cent to enter general practice, and 28 per cent were undecided.

It is of interest to speculate whether all medical schools should be encouraged to conduct such polls annually. A knowledge of the trend of student interest should prove helpful to a school in advising its students. It would also assist the school in reappraising from time to time the influence that its educational program was having on its students in their choice of a career.

Clinical Clerkships

During the last fifteen years there has been a definite trend to scheduling clerkships on inpatient services in the third year of the medical school course. It has been felt that this arrangement is the most satisfactory for providing close supervision and guidance of the student at the time when he is just beginning his work with patients. After serving a well supervised inpatient clerkship, the student should be in a position to derive more benefit from work in the outpatient department, where in general he must work more independently of his instructors. Scheduling the clerkships in the third year also has the advantage of allowing more flexibility in planning the curriculum of the fourth year, since the student enters that year with his basic clinical instruction completed or nearly completed. He can then be given the opportunity to pursue advanced, elective or special courses which he would not have been prepared to take as a third year student and for

which there would not be time in the fourth year if the principal clerkships were all postponed to that year.

In 1948-1949 students will serve clerkships on inpatient services in general medicine during the third year in 57 of the 70 medical schools in this country. In 31 schools, the inpatient clerkship will be given only in the third year. In 26 schools it will extend over the third and fourth years.

In general surgery during 1948-1949, clerkships are scheduled for the third year in 48 schools. Twenty of these schools also provide work with inpatients during the fourth year.

Inpatient clerkships in pediatrics will be given in the third year in 47 schools. Fifteen of these schools also have inpatient clerkships in the fourth year.

The clerkship in obstetrics falls entirely in the third year in 20 schools, is limited to the fourth year in 31 schools and is given in both the third and fourth years in 19 schools.

R.O.T.C. Programs in Medical Schools

Forty-nine medical schools and schools of the basic medical sciences have established or are in the process of establishing R.O.T.C. programs. During 1947-1948 somewhat more than 5 per cent of the total student body in the United States was enrolled in these programs.

New Medical Schools

No new medical schools opened during the past year. The University of Washington School of Medicine in Seattle admitted its second freshman class in the fall of 1947. This school is planning to have its full four year program in operation by the fall of 1949 and to graduate its first class in 1950. The organization of the medical school of the University of California in Los Angeles is continuing. Faculty appointments are being made and a building program is being developed. The school has not yet announced the date on which it will open.

Among the two year schools, West Virginia during the past year has been giving active consideration to expanding to a four year program. North Carolina has received authorization from the legislature to expand and is proceeding with the construction of a teaching hospital which will probably be completed by 1951. The Board of Curators of the University of Missouri is studying plans whereby that school can establish a four year program. The other two year schools have no immediate plans for expansion, although two of them, Mississippi and North Dakota, are still actively studying the problem.

Interest in the possibility of establishing new schools of medicine continues to be displayed by various groups in different parts of the country. No definite plans for a new school, however, were announced during the past year.

Survey of Medical Education

In the last Educational Number it was announced that the Council on Medical Education and Hospitals and the Association of American Medical Colleges would undertake a comprehensive survey of medical education in this country. During the past year the two organizations appointed a committee to conduct the survey and prepare and publish a report. The chairman of the committee is President Alan Valentine of the University of Rochester. The other members are Drs. Arthur C. Bachmeyer, Herman G. Weiskotten, Joseph

C. Hinsey, Victor Johnson, Fred C. Zapffe ex officio and Donald G. Anderson ex officio.

The committee has been active during the past year in formulating plans for the survey and has made the following statement concerning the purpose and plan of the survey:

The objectives of the study shall be to evaluate the present programs and determine the future responsibilities of medical education in its broadest aspects for the purpose of:

1. Improving medical education to better meet the over-all needs of the American people for
 - (a) The prevention of disease
 - (b) The restoration, so far as possible, to health of all those who suffer illness or injury, and
 - (c) The maintenance of the best standards of physical and mental health of all the people.

INTERNSHIPS AND RESIDENCIES

The following internships and residency training programs have been approved since the publication of the list of Approved Residencies and Fellowships in THE JOURNAL, May 1, 1948. Those designated with an asterisk (*) have been granted temporary approval in accordance with the plan announced in THE JOURNAL, April 20, 1946, page 1088. Many of the residencies recognized on a temporary basis have been inspected

2. Assessing the degree to which medical schools are meeting the needs of the country for physicians.
 3. Promoting the advancement of knowledge in the field of medical science, and
 4. Better informing the public concerning the nature, content and purposes of medical education.
- The study should encompass the following:
1. An inventory of the existing situation.
 2. Determination of the need for changes and improvements.
 3. Conclusions and recommendations based on the foregoing.
 4. Proposals for ways and means of carrying out the recommendations.

The survey will be initiated during the coming academic year. It is anticipated that it will require three years to complete.

by members of the Council's staff and are now under consideration for transfer to the regularly approved list. Several hospitals not included in the following list have also been surveyed by representatives of the Council and have been recommended for residency approval. These hospitals will be notified as soon as final action on their applications has been completed by the Council and the respective specialty boards.

POSTGRADUATE AND CONTINUATION COURSES FOR PHYSICIANS

Since 1937 the Council on Medical Education and Hospitals has published periodically in THE JOURNAL lists of postgraduate continuation courses offered by educational institutions throughout the country. These listings include courses of a review and refresher nature as well as formal basic science courses in preparation for specialty board certification. The courses are for variable periods from a few days to a year or longer. Some are concentrated full time courses and others are part time. In the June 19, 1948 issue of THE JOURNAL more than 850 courses covering the period from July 1, 1948 to Jan. 15, 1949 are listed. Interest in postgraduate courses is at an all time peak and appears still to be increasing. During the year July 1, 1947 to June 30, 1948 a total of 1,800 courses were offered. This represented an increase of 437 over the preceding annual period. State medical societies, medical schools,

hospitals, state and city boards of health and special societies continue to be active in providing leadership in developing this increasingly popular undertaking in medical education. Institutions offering this type of training are invited to announce such courses in the semiannual lists compiled by the Council.

With the exception of the formal basic science courses, these continuation or review courses are not designed to prepare physicians for certification in the specialties by the American boards. Some opportunities are offered, however, for review work in preparation for the examinations of the specialty boards. Many are applicable to the educational benefits provided physician veterans.

In the following paragraphs mention is made of some of the recent and noteworthy developments in post-

graduate education. An analysis of the courses offered during the period July 1, 1947 to July 1, 1948 is also presented.

Recent Developments

Cancer symposiums extending over several days are being sponsored in the metropolitan and nonmetropolitan areas of California by the county medical societies, the Cancer Commission of the California Medical Association, the State Department of Public Health and the California Division of the American Cancer Society.

The Section of Maternal and Child Health of the Louisiana State Department of Health has developed refresher courses in obstetrics and pediatrics in cooperation with the medical schools in New Orleans. The courses covered two weeks, each course being limited to twenty physicians. Tuition, transportation and expenses were paid by the State Health Department.

Postgraduate courses in pediatrics of two weeks' duration, designed primarily for physicians in general practice, are offered every month to physicians in Michigan without charge through the cooperation of the Michigan Department of Health, the Michigan State Medical Society and the departments of pediatrics and postgraduate medicine of the University of Michigan.

Postgraduate instruction throughout the state of New York is arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

will be given in November at the College of Medical Evangelists under the auspices of the Los Angeles Urological Society.

Analysis of Courses Offered in 1947-1948

In presenting this analysis of postgraduate courses which have been offered during the annual period July 1, 1947 to June 30, 1948 the statistical summaries are divided into three groups. Short review courses of five days or less are discussed, followed by courses of more than five days' duration and, lastly, a group including clinical conferences, graduate assemblies, study courses and courses of a chautauqua nature.

Short Review Courses.—Thirty-one states and the District of Columbia provided opportunities of five days' duration or less for physicians to continue professional study in or near their home communities. There were 496 courses given in these states as follows:

Alabama.....	2	Minnesota.....	5
Arizona.....	1	Missouri.....	9
California.....	47	New York.....	105
Colorado.....	6	North Carolina.....	6
Connecticut.....	11	North Dakota.....	2
District of Columbia.....	3	Ohio.....	10
Florida.....	2	Oklahoma.....	36
Georgia.....	2	Oregon.....	1
Illinois.....	18	Pennsylvania.....	75
Indiana.....	13	South Carolina.....	2
Iowa.....	13	Tennessee.....	10
Kansas.....	22	Texas.....	11
Kentucky.....	6	Vermont.....	3
Louisiana.....	6	Virginia.....	4
Massachusetts.....	9	Washington.....	1
Michigan.....	25	Wisconsin.....	20
Total.....			496

TABLE 21.—Courses Offered and Attendance

	1945-1946			1946-1947			1947-1948		
	Total Courses	Number Reporting Attendance	Attendance	Total Courses	Number Reporting Attendance	Attendance	Total Courses	Number Reporting Attendance	Attendance
Short review courses (5 days or less).....	154	128	4,140	239	205	16,274	496	478	31,569
Courses of less than a year and more than 5 days.....	1,070	1,043	19,991	1,201	1,137	23,062	1,379	1,183	24,878
Clinical conferences, graduate assemblies, study and chautauqua courses.....	52	52	21,824	21	21	20,475	25	25	26,356
Totals.....	1,276	1,223	45,955	1,551	1,363	59,811	1,900	1,686	82,803

A series of educational exercises consisting of clinics and pathologic conferences at hospitals throughout the state are regularly scheduled by the Rhode Island Medical Society. All members of the society are privileged to attend.

A course in physical medicine and rehabilitation was conducted by the University of Texas Medical Branch. The course was designed for the general practitioner and specialist interested in the more effective use of physical medicine and included a roster of twenty recognized authorities as guest speakers. Instruction was provided in the theory and technic of application of the various physical agents, as well as demonstrations and motion pictures.

The American Academy of Ophthalmology and Otolaryngology conducts home study courses for graduates in medicine who are practicing or are preparing to take up the practice of these specialties.

The American Urological Association is establishing courses of graduate instruction in urology. These courses are to be given in eight or ten areas in various parts of the country and will cover a series of daily lectures over a period of a week. Emphasis will be placed on the basic sciences and their application to the problems of urology. The first course arranged

The subjects of these 496 courses included:

Allergy	Malignant diseases
Anatomy	Medicine, general
Anesthesiology	Neurology and psychiatry
Arthritis	Obstetrics and gynecology
Bacteriology	Ophthalmology
Basic sciences	Orthopedic surgery
Biochemistry	Otolaryngology
Cardiovascular disease	Otology
Chest diseases	Otorhinolaryngology
Dermatology and syphilology	Pathology
Diabetes	Pediatrics
Electrocardiography	Physical medicine
Electroencephalography	Physiology
Endocrinology	Poliomyelitis
Endoscopy	Proctology
Fractures	Public health
Gastroenterology	Radiology
Genetics and anthropology	Surgery, general
Hematology	Therapy
Industrial health	Urology
Internal medicine	Venerical disease

The courses varied in length from sessions of one-half hour to five days' full time and consisted of organized courses, daily set clinics on patients in the wards and evening lectures with emphasis on recent developments. Of the 496 courses reported, 125 covered five days' full time, 65 were four day courses, 59 were three day courses, 49 two days and 43 one full day. In 60 instances the length of the course was variable. The remainder of the courses were reported by lectures, sessions or hours. The type of instruction was didactic,

clinical or both. The instructors were chosen from physicians practicing in the state in which the courses were offered as well as from out of the state. Medical school faculty members participated in 178 of the courses. The facilities used included hospitals, clinics, medical schools and hotels.

These offerings were held in every month, the majority being given in January, March, September and October. Thirty-two were offered continuously throughout the year, while 52 were arranged at the convenience of the applicant. Fifty-five were available for specialists only. Fees ranged from \$3 to \$300. The majority were less than \$50. For 84 courses no fee was charged.

The attendance reported for 478 courses was 31,569. For 18 courses no enrolment figures were compiled.

This type of instruction is in great demand, as evidenced by the fact that the attendance almost doubled the reported attendance last year.

Courses of More than Five Days.—In centers where ample clinical facilities are available, 1,279 graduate courses of more than five days' duration were offered in thirty-four states and the District of Columbia during 1947-1948. These states and the number of courses which were given in each state are as follows:

Arkansas.....	3	Mississippi.....	2
California.....	64	Missouri.....	6
Colorado.....	6	Nebraska.....	3
Connecticut.....	19	New Jersey.....	2
District of Columbia.....	47	New York.....	513
Florida.....	2	North Carolina.....	1
Georgia.....	10	Ohio.....	4
Illinois.....	191	Oklahoma.....	8
Indiana.....	3	Oregon.....	19
Iowa.....	12	Pennsylvania.....	61
Kansas.....	6	South Carolina.....	2
Kentucky.....	3	Tennessee.....	3
Louisiana.....	16	Texas.....	16
.....	6	Vermont.....	4
.....	116	Virginia.....	7
Michigan.....	26	Washington.....	12
Minnesota.....	11	Wisconsin.....	12
Total.....			1,279

These courses consisting of refresher courses of more than five days to intensive courses extending over one year were offered in the following subjects:

Allergy	Medicine, general
Anatomy	Neurology and psychiatry
Anesthesiology	Nutrition
Arthritis	Obstetrics and gynecology
Bacteriology	Ophthalmology
Basic sciences	Orthopedic surgery
Biochemistry	Otolaryngology
Cardiovascular disease	Otorhinolaryngology
Chemistry	Otology
Chest diseases	Pathology
Dermatology and syphilology	Pediatrics
Diabetes	Pharmacology
Electrocardiography	Physical medicine
Electroencephalography	Physiological chemistry
Endocrinology	Physiology
Endoscopy	Poliomyelitis
Fractures	Proctology
Gastroenterology	Public health
Hematology	Radiology
Industrial health	Surgery, general
Internal medicine	Therapy
Legal medicine	Urology
Malignant diseases	Veneral disease

The length of the full time courses varied from six days to one month for 425 courses. There were offered 234 courses ranging in length from one to four months and 224 from five to twelve months. There were 16 one year courses and 2 each given for two and three years. The remainder (376) specified the length of the course in hours, sessions, seminars, semesters or quarters.

The description of these intensive courses indicated that instruction was both clinical and didactic. Instruction was both didactic and clinical for 604 courses, didactic only for 81 and clinical only for 86. The remainder did not specify the type of instruction.

In presenting these courses, hospital facilities were used for 744 courses, medical schools for 571 courses and clinics for 425. In many instances two or all three of these sources were used in presenting an individual course. Hotel and other facilities were used for 89 courses.

The faculties of medical schools served as instructors in 472 courses. Additional instructors were specialists in their field, chosen mainly (in 558 instances) from physicians residing within the state in which the course was given, but included also physicians from outside the state.

Courses were offered during every month, and in 44 instances they were arranged to suit the convenience of physician-students. There were 95 courses given for specialists only. Fees varied from \$1 to \$1,000. For 43 courses no fee was charged.

The attendance reported for 1,183 of the 1,279 courses given in 1947-1948 was 24,878.

Sponsoring and Contributing Agencies.—One hundred and ninety-four agencies participated in the sponsoring of both the short review courses and the longer courses. These included 59 medical schools, 43 special societies, 29 hospitals, 22 state societies, 10 graduate schools of medicine, 14 county societies, 13 state health departments, 3 universities and the United States Public Health Service.

Seventeen agencies, while not responsible for the development of these opportunities, were reported as contributing agencies. These included the W. K. Kellogg Foundation, the Commonwealth Fund, Veterans Administration, Rockefeller Foundation and the National Foundation for Infantile Paralysis.

Clinical Conferences, Graduate Assemblies, Study Courses and Chautauqua Courses.—In fifteen states, there were twenty-five such opportunities offered. This type of training varied in length from one day sessions to two weeks for conferences, assemblies and study courses. In eight states, chautauqua courses were held at various times throughout the states in from four to twelve centers. Contributing agencies were speakers' bureaus, medical schools, state and county medical societies, state health departments and special societies. The majority surveyed topics in general medicine and surgery. Other subjects covered were pediatrics, ophthalmology and otolaryngology, psychosomatic medicine, obstetrics and gynecology. Instruction was both didactic and clinical. The facilities of hospitals, clinics and medical schools were used. For this type of instruction no fee was charged or a small registration fee. The attendance numbered 26,356.

Summary.—In thirty-five states and the District of Columbia some form of continuation study for practicing physicians was provided during 1947-1948. Table 21 summarizes the recorded enrolment for the year with comparative figures for two preceding years. The total for last year (82,803) represents the greatest number to seek such training in a given year. It exceeded the attendance during 1946-1947 by 22,992 and that of the year 1945-1946 by 36,848.

The offering of such opportunities to an increasing extent, as presented by these figures, indicates an extensive expansion and use of facilities of medical schools and hospitals. It represents also the desires of almost half of the entire physician population to improve their knowledge of newer technics of practice in a single year. Great credit is due all who participate in this remarkable program to improve the care of the people of our country.

APPROVED MEDICAL SCHOOLS IN THE UNITED STATES

ALABAMA

Birmingham

Medical College of Alabama.—Established in 1943 as a division of the University of Alabama. Located in Birmingham in 1944. In 1945 assumed title to Jefferson Hospital and Hillman Hospital, Birmingham. The Medical College of Alabama cares for all indigent patients of the county and city, maintenance of which is paid to the university on a per diem basis by the county. In 1943 appropriation included one million dollars for the building of a new medical school which will be erected as early as possible, and temporary quarters are now in the Jefferson-Hillman Hospital. First instruction in the Medical College of Alabama started June 4, 1945, with a junior class and this class was graduated in October, 1946. On October 8, 1945, the School of the Basic Medical Sciences on the University Campus, established in 1920, and its faculty, was absorbed into the new Medical College of Alabama. The medical college is coeducational. Minimum entrance requirements are three years of college work. Tuition is as follows: for legal residents of Alabama \$400 per academic year plus incidental fees of \$20. Non-residents of the state are charged an additional \$100 each session. The registration for the 1947-1948 session was 132. No senior class was in session. The last session began Oct. 6, 1947 and ended June 12, 1948. The next session for all four classes will start Sept. 13, 1948, and will end June 7, 1949. The Dean is Roy R. Kracke, M.D.

ARKANSAS

Little Rock

University of Arkansas School of Medicine, 1209 McAlmont Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The curriculum covers four sessions of nine months each. Entrance requirements are three years of collegiate work. The B.S. degree is conferred at the end of the second year. The fees for the four years for residents of Arkansas are \$380 a year; nonresidents are charged \$505 a year. The registration for the 1947-1948 session was 274; graduates 55. The last session began Sept. 21, 1947, and ended June 18, 1948. The next session will begin Sept. 27, 1948, and will end June 17, 1949. The Dean is Joseph T. Roberts, M.D.

CALIFORNIA

Berkeley-San Francisco

University of California Medical School, University Campus, Berkeley; Medical Center, San Francisco 22.—Organized in 1864 as the Toland Medical College. The first class graduated in 1864. In 1873 it became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of the University of Southern California, at Los Angeles, became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged and elective chairs in homeopathic materia medica and therapeutics were provided. Coeducational since organization. Three years of collegiate work are required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The medical course consists of four academic years, each containing two semesters of sixteen weeks each. The fees are \$320 per academic year. Nonresidents are charged \$250 additional each year. The registration for the 1947-1948 session was 283; graduates 63. The last session began Sept. 22, 1947 and ended June 17, 1948. The next class will begin Sept. 13, 1948 and will end June 16, 1949. The Dean is Francis Scott Smyth, M.D., San Francisco.

Loma Linda-Los Angeles

College of Medical Evangelists, Loma Linda; Boyle and Michigan Avenues, Los Angeles 33.—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda; the clinical departments at Los Angeles. Coeducational since organization. Three years of collegiate work are required for admission. The freshman, sophomore and junior years consist of nine month academic sessions and the senior year will have in addition to the nine month session a seven weeks' clinical clerkship during the summer between the junior and senior years. A twelve month internship in an approved hospital is required. The yearly tuitions including fees are respectively, \$730, \$719, \$737 and \$745. The registration for 1947-1948 was 319; graduates 87. The last session for freshman, sophomore and junior students began on Sept. 21, 1947 and ended June 30, June 30 and June 11, 1948, respectively. The senior session began June 22, 1947 and was completed June 13, 1948. The next session for freshman and sophomore students will begin Sept. 12, 1948, junior students Sept. 19, 1948 and senior students June 13, 1948 and will end June 16, June 23, June 10, and June 12, 1949 respectively for the four classes. The president is George T. Harding, M.D., Los Angeles. The deans are Harold Shryock, M.D., Loma Linda, and W. F. Norwood, Ph.D., Los Angeles.

Los Angeles

University of Southern California School of Medicine, 3551 University Avenue, Zone 7.—Organized in 1895 as the 'University' of Southern California College of Medicine. First class graduated in 1888. In 1908 it became the Los Angeles Medical Department of the University of California. In 1909 the College of Physicians and Surgeons, established in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920; reorganized in May 1928, under present title. Entrance requirements are approximately 90 semester hours. An internship is required for graduation. Coeducational since organization. Annual fees amount to approximately \$600. The registration for 1947-1948 was 251; graduates 58. The last session began Sept. 15, 1947 and ended June 12, 1948. The next session will begin Sept. 13, 1948 and will end June 11, 1949. The Dean is Burrell O. Raulston, M.D.

Stanford University-San Francisco

Stanford University School of Medicine, University Campus, Stanford University; 2398 Sacramento Street, San Francisco. The main buildings are in San Francisco. The laboratories of anatomy, bacteriology and experimental pathology, chemistry and physiology are located on the campus at Stanford University, which is thirty miles southeast of San Francisco adjoining the City of Palo Alto. The post office is Stanford University. Organized in 1908, when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. Three years of collegiate work are required for admission. The quarter plan is in operation. An internship is a requirement for graduation. The average fee for each of the four years is \$699. The registration for 1947-1948 was 242; graduates 57. The last session for all classes began Sept. 29, 1947 and ended June 9, 1948. The next session will begin Sept. 27, 1948 and will end June 15, 1949. The Dean is Loren R. Chandler, M.D.

COLORADO

Denver

University of Colorado School of Medicine, 4200 East Ninth Avenue.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan. 1, 1911. Coeducational since organization. The entrance requirements are ninety semester hours of collegiate work. The fees average \$150 per academic year. Nonresidents are charged \$225 additional each year. The registration for 1947-1948 was 233; graduates 62. The last session began Sept. 29, 1947 and ended June 14, 1948. The next session will begin Sept. 27, 1948 and will end June 13, 1949. The Dean is Ward Darley, M.D.

CONNECTICUT

New Haven

Yale University School of Medicine, 333 Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812; instruction began in 1813; first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1881, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. Coeducational since 1916. The requirements for admission are three years collegiate work. The fees average \$750 per academic year. The registration for 1947-1948 was 222; graduates 55. The last session began Sept. 22, 1947 and ended June 16, 1948. The next session will commence Sept. 22, 1948 and will end June 16, 1949. The Dean is C. N. H. Long, M.D.

DISTRICT OF COLUMBIA

Washington

Georgetown University School of Medicine, 3800 Reservoir Road, N. W., Zone 7.—Organized in 1851. First class graduated in 1852. The degree of Bachelor of Arts or Bachelor of Science or its equivalent from an approved college of arts and sciences is required for admission of non-veterans, but veterans may be admitted with a minimum of 90 semester hours of credit. The fees average \$635 per academic year. Registration for 1947-1948 was 369, graduates 75. The last session for freshmen and sophomores began Sept. 22, 1947 and ended May 29, 1948; the junior class began Sept. 22, 1947 and ended May 21, 1948 and the senior class began Sept. 22, 1947 and ended June 14, 1948. The next session for freshmen and sophomores will begin Sept. 20, 1948 and will end May 28, 1949, the juniors will be in session from Aug. 30, 1948 to May 28, 1949; the senior session began June 1, 1948 and will end June 13, 1949. The Dean is Rev. Paul A. McNally, S.J., Ph.D.

George Washington University School of Medicine, 1335 H Street, N. W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name "National Medical College." Classes were graduated in 1826 and in all subsequent years except in 1834-1838 and 1861-1863 inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it

absorbed the National University Medical Department. In 1904 by an Act of Congress the title of George Washington University was granted to the institution. Coeducational since 1881. Ninety semester hours of college work are required for admission. The fees average \$600 per academic year. The registration for 1947-1948 was 315; graduates 80. The last session began Sept. 15, 1947 and ended May 26, 1948. The next session will begin Sept. 20, 1948 and will end June 1, 1949. The Dean is Walter A. Bloodorn, M.D.

Howard University College of Medicine, Fifth and W Streets, N. W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. The fees are, respectively, \$352.50; \$317.50; \$337.50; \$337.50. The registration for 1947-1948 was 271; graduates 64. The last session began Sept. 27, 1947 and ended June 1, 1948. The next session will begin Sept. 25, 1948 and will end June 3, 1949. The Dean is Joseph L. Johnson, M.D.

GEORGIA

Augusta

University of Georgia School of Medicine, University Place.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1929. After 1873 it was known as the Medical Department of the University of Georgia. On July 1, 1933, the name was changed to the University of Georgia School of Medicine. Property transferred to the University in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. Three years of collegiate work are required for admission. The fees average \$225 per academic year for residents of Georgia, nonresidents \$325. Only bona fide residents of Georgia admitted (with exception of A.S.T. and V-12 Program students during World War II). The registration for the 1947-1948 session was 290; graduates 66. The 1947-1948 session for the senior class began April 3, 1947 and ended March 22, 1948; the freshman, sophomore and junior classes began September 11, 1947 and ended June 19, 1948. The next session will begin Sept. 9, 1948 and will end June 20, 1949. The Dean is G. Lombard Kelly, M.D.

Emory University

Emory University School of Medicine.—Organized in 1851 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with Atlanta School of Medicine (organized in 1905), resuming the name of Atlanta Medical College. Became the School of Medicine of Emory University in 1915. Three years of collegiate work are required for admission. The course of study is four academic years; 34 weeks each in the 1st and 2nd years; 36 weeks in the 3rd year; 40 weeks in the 4th year. The fees for each of the four academic years are \$600. The registration for 1947-1948 was 210; graduates 48. The last session for freshmen and sophomores began Sept. 18 and 22, 1947 and ended June 5, 1948; the last session for juniors began Sept. 2, 1947 and ended June 5, 1948; the last session for seniors began Aug. 1, 1947 and ended June 5, 1948. The next session for freshmen and sophomores will begin Sept. 23 and 27, 1948 and will end June 4, 1949; the next session for the junior class will begin Sept. 7, 1948 and will end June 4, 1949; the senior session began Aug. 2, 1948 and will end June 4, 1949. The Dean is R. Hugh Wood, M.D.

ILLINOIS

Chicago

Northwestern University Medical School, 303 East Chicago Avenue.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The requirement for admission is 85 semester hours of collegiate work. The B.S. in medicine degree may be conferred before the end of the senior year. A hospital internship is required for graduation. The total fees are \$600 each year. The registration for 1947-1948 was 520; graduates 143. The last session began Sept. 26, 1947 and ended June 12, 1948. The next session will begin Sept. 24, 1948 and will end June 11, 1949. The Dean is J. Roscoe Miller, M.D.

Stritch School of Medicine of Loyola University, 706 South Wolcott Avenue.—Organized in 1915 by acquisition of Bennett Medical College which had been organized in 1869. Facilities enlarged by the acquisition of Chicago College of Medicine and Surgery. Faculties in basic sciences put on full time basis and assumed name of Loyola University School of Medicine in 1917. Operated as an organic part of Loyola University. Name officially changed to Stritch School of Medicine of Loyola University on April 15, 1948. Coeducational since organization. Ninety semester hours of collegiate work are required for admission. The fees for the academic year beginning Sept. 27, 1948 will be \$675. The registration for 1947-1948 was 277; graduates 67. The last session for freshmen, sophomores and juniors began Sept. 22, 1947 and ended June 26, 1948;

the session for seniors began April 8, 1947 and ended March 23, 1948. The next session for freshmen, sophomores and juniors will begin Sept. 27, 1948 and will end June 25, 1949. The next session for seniors will begin Sept. 13, 1948 and will end June 4, 1949. The Dean is James J. Smith, M.D.

University of Chicago, The School of Medicine, Fifty-Eighth Street and Ellis Avenue.—Organized in 1924, as a part of the Ordan Graduate School of Science of the University of Chicago. In 1932, when the University of Chicago reorganized its departments, the medical departments were included in the Division of Biological Sciences. The work the first two years in the medical courses has been given on the University Quadrangles since 1899; but the last two years were offered only at Rush Medical College which was affiliated with the university until 1927 when actual work in the clinical departments on the campus began. After that time candidates for the degree of Doctor of Medicine could take the work of the first two years on the campus and the work of the third and fourth years either on the campus or at the Rush Medical College. In June 1940 Rush Medical College became affiliated with the University of Illinois College of Medicine. All undergraduate instruction is now given only on the campus of the University of Chicago. The requirements for admission are 90 semester hours of collegiate work. The B.S. degree may be obtained during the second year. The curriculum covers twelve quarters of work. Seventy-two students are admitted to the first year class each year. The tuition fee averages \$690. The registration for 1947-1948 was 232; graduates, 51. Quarters begin in March, June, September and December of each year. All correspondence relating to general policies should be addressed to A. C. Bachmeyer, M.D., Associate Dean of the Biology Division, and that pertaining to student affairs to F. J. Mullin, Ph.D., Dean of Students.

University of Illinois College of Medicine, 1853 West Polk Street, Zone 12.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was canceled in June 1912, and was restored in March 1913, when the present title was assumed. The staff of the Rush Medical College was incorporated in the University of Illinois College of Medicine in 1942 and at the same time Presbyterian Hospital, Chicago, became a teaching unit of the university. Coeducational since 1898. Three years of collegiate work are required for admission. The B.S. in medicine degree may be conferred at the end of the second year. The fees for residents of Illinois average \$292 per academic year; nonresidents pay an additional fee of \$150. The registration for the 1947-1948 session was 634; graduates, 147. The last session began Sept. 29, 1947 and ended June 17, 1948. The next session will begin Sept. 27, 1948 and will end June 17, 1949. The Dean is John B. Youmans, M.D.

INDIANA

Bloomington-Indianapolis

Indiana University School of Medicine, Bloomington; 1040 West Michigan Street, Indianapolis.—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907 by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The B.S. degree in anatomy and physiology is conferred. Three years of college work are required for admission. The work of the first two semesters is given at Bloomington; the remainder of the work at Indianapolis. Regular fee for two semesters of work is \$221 for residents of Indiana and \$426 for nonresidents. The registration for the 1947-1948 session was 396; graduates 84. The last session began Sept. 22, 1947 and ended June 10, 1948. The next session will begin Sept. 20, 1948 and will end June 12, 1949. The Dean is John D. Van Nuys, M.D., Indianapolis.

IOWA

Iowa City

State University of Iowa College of Medicine, University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. Three years of collegiate work are required for admission. The B.A. degree in the combined course of liberal arts and medicine is conferred. The tuition fee is \$230 each year for residents of Iowa and \$490 for nonresidents. The registration for 1947-1948 was 278; graduates 57. The last session for freshmen, sophomores and juniors began Sept. 22, 1947 and ended June 5, 1948; the last session for seniors began March 24, 1947 and ended March 13, 1948. The next session will begin Sept. 23, 1948 and will end on June 10, 1949. The Dean is Mayo Hamilton Soley, M.D.

KANSAS

Lawrence-Kansas City

University of Kansas School of Medicine, Lawrence; 39th Street and Rainbow Boulevard, Kansas City.—Organized in 1880. It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-

Chirurgical College, founded in 1897. Absorbed Kansas Medical College of Topeka in 1913. The first class graduated in 1906. The clinical courses are given in Kansas City. At present the first year and one-half of the medical course is given on the University campus at Lawrence, Kansas. The class is transferred to the Kansas City, Kansas, campus in the middle of the second year where the balance of the course is given. Coeducational since 1880. The requirement for admission is three years of collegiate work. The fees are \$300 per year; the nonresident fees are \$600 per year. The registration for 1947-1948 was 308; graduates 56. The last session began Sept. 17, 1947 and ended June 3, 1948. The next freshman and sophomore classes will begin Sept. 20, 1948 and end June 2, 1949. The session for the junior and senior classes began June 14, 1948 and will end June 2, 1949 with three-fourths of each class in school all the time and one-fourth on vacation each quarter. The Dean is Franklin D. Murphy, M.D., Kansas City.

KENTUCKY

Louisville

University of Louisville School of Medicine, 101 West Chestnut Street, Zone 2.—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838, and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department; in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. In 1922 it changed its name to the University of Louisville School of Medicine. Coeducational since organization. Two years of collegiate work are the minimum requirements for admission. Preference is given applicants with a degree or three college years leading to a degree. Fees are \$450 for residents of Louisville and Jefferson County and \$600 for nonresidents, per school year. The registration for 1947-1948 was 323; graduates 144. The school year is divided into two semesters and students are accepted for matriculation only at the beginning of the first semester. The last session began Sept. 22, 1947 and ended June 15, 1948. The next session begins on Sept. 22, 1948, and will end on June 14, 1949. The Dean is John Walker Moore, M.D.

LOUISIANA

New Orleans

Louisiana State University School of Medicine, 1542 Tulane Avenue, Zone 13.—Organized January 1931 as Louisiana State University Medical Center. Present title in 1939. Coeducational. First session October 1931 with students of first and third years. Course covers four sessions of not less than 36 weeks each. A minimum of three years collegiate work is required for admission. Total fees, \$120 each year for residents of Louisiana; additional tuition of \$400 each year for nonresidents. The registration for 1947-1948 was 308; graduates 80. The last session for freshman, sophomore and junior students began Sept. 4, 1947 and ended June 5, 1948; the senior session began April 9, 1947 and ended May 22, 1948. The next session for all classes will begin Sept. 7, 1948 and end June 4, 1949. The Dean is Vernon W. Lippard, M.D.

Tulane University of Louisiana School of Medicine, 1430 Tulane Avenue.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years except 1863-1865, inclusive. It became the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. A minimum of three years of collegiate work is required for admission. Total fees average \$650 per academic year. The registration for the 1947-1948 session was 477; graduates 97. The last session began on Sept. 2, 1947 and ended on June 2, 1948. The next session will begin Sept. 1, 1948 and will end June 1, 1949. The Dean is Maxwell E. Lapham, M.D.

MARYLAND

Baltimore

Johns Hopkins University School of Medicine, 710 North Washington Street.—The nucleus of a Medical Faculty was constituted in 1883. Systematic postgraduate instruction in pathology and bacteriology was begun in 1886. School was fully organized and opened in 1893. The first class graduated in 1897. Coeducational since organization. The requirement for admission is a college degree. The course extends over four years of eight and one-half months each. The fees average \$628 per academic year. The registration for 1947-1948 was 297; graduates 78. The last session began on Sept. 29, 1947 and ended June 8, 1948. The next session will begin on Oct. 4, 1948 and will end June 14, 1949. The Dean is Alan M. Chesney, M.D.

University of Maryland School of Medicine and College of Physicians and Surgeons, Lombard and Greene Streets, Zone 1.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged with it in 1913. In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed. Coeducational since 1918. Three years of college work is required for admission. The tuition fees average \$513 for residents of the state; for nonresidents \$150 additional. The registration for 1947-1948 was 322; graduates 77. The last session began Sept. 18, 1947 and ended June 5, 1948. The next session will begin Sept. 16, 1948 and will end June 4, 1949. The Dean is H. Boyd Wylie, M.D.

MASSACHUSETTS

Boston

Boston University School of Medicine, 80 East Concord Street, Zone 18.—Organized in 1873 as a homeopathic institution. In 1874 the New England Female Medical College, founded in 1818, was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. Applicants are required to present a minimum of three years of premedical work. Total fees average \$800 per year. The registration for 1947-1948 was 235; graduates 54. The last session for freshmen, sophomores and juniors began Sept. 15, 1947 and ended June 5, 1948. The last senior class began June 16, 1947 and ended June 7, 1948. The present senior class began June 14, 1948 and will end June 6, 1949. All other classes will be enrolled Sept. 13, 1948 and the session will end May 28, 1949. The Dean is James M. Faulkner, M.D.

Harvard Medical School, 25 Shattuck Street, Zone 15.—Organized in 1782. The first class graduated in 1788. Two years of collegiate work are required for admission. The fees average \$830. The registration for 1947-1948 was 504; graduates 140. The last session began Sept. 22, 1947 and ended on June 10, 1948. The next session will begin Sept. 27, 1948 and will end June 23, 1949. The Dean is C. Sidney Burwell, M.D.

Tufts College Medical School, 416 Huntington Avenue, Zone 15.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. A bachelor's degree is required for admission. Enrollment is generally limited to residents of the New England states. The course covers four years. The total fees for each of the four years, respectively, are \$685, \$680, \$680, \$690. The registration for 1947-1948 was 394; graduates 91. The last session for freshmen, sophomores and juniors began Sept. 24, 1947; for seniors June 9, 1947 and all classes ended June 20, 1948. The present session began for the seniors on June 14, 1948 and for the other classes will begin Sept. 22, 1948 and will end June 19, 1949. The Dean is Dwight O'Hara, M.D.

MICHIGAN

Ann Arbor

University of Michigan Medical School—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1913. Coeducational since 1870. The entrance requirements are ninety semester hours. The fees average \$280 per academic year; for nonresidents \$500 a year. The registration for 1947-1948 session was 476; graduates 132. The last session began Sept. 22, 1947 and ended June 12, 1948. The next session will begin Sept. 20, 1948 and will end June 11, 1949. The Dean is Albert C. Furstenberg, M.D.

Detroit

Wayne University College of Medicine, 1512 St. Antoine Street, Zone 1.—Organized as the Detroit College of Medicine in 1885 by consolidation of the Detroit Medical College (organized in 1868) and the Michigan College of Medicine (organized in 1879). Reorganized with the title of Detroit College of Medicine and Surgery in 1913. The first class graduated in 1869. In 1918 it became a municipal institution under the control of the Detroit Board of Education. In 1934 the name was changed by action of the Detroit Board of Education to Wayne University College of Medicine, as a part of the program of consolidation of the Detroit city colleges into a university system. Coeducational since 1917. Entrance requirement is 90 semester hours from an accredited college or university. Until further notice, enrollment is limited to residents of the State of Michigan. The fees average \$525 for the school year. The registration for 1947-1948 was 226; graduates 60. The last session began Sept. 15, 1947 and ended June 12, 1948. The next session will begin Sept. 15, 1948 and will end June 18, 1949. The Dean is Hardy A. Kemp, M.D.

MINNESOTA

Minneapolis

University of Minnesota Medical School, Zone 11.—Organized in 1883 as the University of Minnesota Medical College of Medicine and Surgery and reorganized in 1888 by absorption of the St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. Coeducational since organization. The entrance requirements are three years of university work. Students are required to meet the requirements for a degree of B.S. or B.A. before receiving the degree of Bachelor of Medicine (M.B.), which is granted at the end of the course. The M.D. degree is conferred after a year of intern work, of advanced laboratory work, or of public health work has been completed. Total fees are \$307.95 per academic year for residents and \$526.95 for nonresidents. The registration for 1947-1948 was 391; graduates 140. The last session began Sept. 29, 1947 and ended June 12, 1948. The next session will begin Sept. 27, 1948 and will end July 23, 1949. The school year of the first three years consists of fall and winter quarters of approximately 11 weeks and a spring quarter of approximately 16 weeks; in the senior year the spring quarter is 11 weeks in length and graduation is in June. The Dean is Harold S. Dield, M.D.

MISSOURI

St. Louis

St. Louis University School of Medicine, 1102 South Grand Boulevard, Zone 1.—Organized in 1901 as the Marion-Sims-Beaumont Medical College by union of Marion-Sims Medical College, organized in 1880, and Beaumont Hospital Medical College, organized in 1886. First class graduated in 1902. It became the Medical School of St. Louis University in 1903. The completion of three years of college study is the minimum admission requirement but students presenting meritorious credits in excess of the minimum are accepted by preference. The fees average \$611 per academic year. The registration for 1947-1948 was 432; graduates, 120. The last session began Sept. 16, 1947 and ended June 1, 1948. The next session will begin Sept. 11, 1948 and will end June 1, 1949. The Dean is Alphonse M. Schwitalla, S.J., Ph.D.

Washington University School of Medicine, Kingshighway and Euclid Avenue, Zone 10.—Organized in 1812 as the Medical Department of St. Louis University. The first class graduated in 1813. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. Coeducational since 1918. Three years of college work is required for admission. The B.S. degree in medicine is conferred at the end of the third or fourth year. The fees average \$605. In 1949 the fees will be increased to \$700. The registration for 1947-1948 was 360; graduates, 90. The last session began on Sept. 15, 1947 and ended June 8, 1948. The next session will begin on Sept. 13, 1948 and will end on June 7, 1949. The Dean is Robert A. Moore, M.D.

NEBRASKA

Omaha

Creighton University School of Medicine, 306 North Fourteenth Street, Zone 2.—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. Ninety semester hours of collegiate work are required for admission. The tuition fees average \$625 per academic year. The registration for 1947-1948 was 244; graduates, 65. The last session began Sept. 26, 1947 and ended June 3, 1948. The next session will begin Sept. 24, 1948 and will end June 2, 1949. The Dean is Percy J. Carroll, M.D.

University of Nebraska College of Medicine, Forty-Second Street and Dewey Avenue, Zone 5.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. Three years of college work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees average \$350 per academic year. The registration for 1947-1948 was 293; graduates, 67. The last session for seniors began March 26, 1947 and ended April 3, 1948. The last session for freshmen, sophomores and juniors began Sept. 15, 1947 and ended June 5, 1948. The next session will begin Sept. 13, 1948 and will end June 4, 1949. The Dean is Harold C. Luehl, M.D.

NEW YORK

Albany

Albany Medical College, 17 New Scotland Avenue.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915 Union University assumed educational control. Coeducational since 1915. The requirement for admission is three years of college work. The fees average \$725 per academic year. The registration for 1947-1948 was 182; graduates 40. The last session began for the freshmen and sophomores on Sept. 29, 1947 and ended June 24, 1948 for the freshmen and June 14, 1948 for the sophomores; the last session for the juniors began April 7, 1947 and ended April 3, 1948, for the seniors June 2, 1947 to May 31, 1948. The present senior class began June 1, 1948 and will end May 31, 1949. The next session for other classes will begin Sept. 27, 1948 and will end June 13, 1949. The Dean is R. S. Cunningham, M.D.

Brooklyn

Long Island College of Medicine, 350 Henry Street, Zone 2.—Chartered in 1930, was originally organized in 1858 as the Long Island College Hospital. From the collegiate department the first class graduated in 1860 and the last class in 1930. The first class of the Long Island College of Medicine was graduated in 1931. It is coeducational. Three years of collegiate work, including specified courses, are required for admission. The fees are \$715 per academic year. The registration for 1947-1948 was 404; graduates 92. The last session for seniors began Sept. 15, 1947 and ended May 29, 1948. The last session for freshmen, sophomores and juniors began on Sept. 22, 1947 and ended on June 12, 1948. The next session begins for freshmen, sophomores and juniors on Sept. 20, 1948 and ends June 10, 1949; for seniors the next session will begin Sept. 13, 1948 and will end June 8, 1949. The President is Jean A. Curran, M.D. The Dean is Duncan W. Clark, M.D.

Buffalo

University of Buffalo School of Medicine, 24 High Street.—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The minimum requirement for admission is three years of col-

legiate work including certain prescribed science subjects. The fees average \$515. The registration for 1947-1948 was 273; graduates 74. The last session began on Sept. 22, 1947 and ended June 19, 1948. The next session will begin Sept. 20, 1948 and will end June 18, 1949. The Dean is Stockton Kimball, M.D.

New York

Columbia University College of Physicians and Surgeons, 630 West One Hundred and Sixty-Eighth Street.—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. Three years of collegiate work are required for admission. Fees average \$650 per academic year. The registration for 1947-1948 was 432; graduates 100. The last session began on June 9, 1947 for juniors and seniors and ended on June 1, 1948. The last session for freshmen and sophomores began on Sept. 11, 1947 and ended June 1, 1948. The present session began on June 7, 1948 and June 1, 1948 respectively, for the juniors and seniors and will end June 1, 1949, and will begin on Sept. 13, 1948 for the freshmen and sophomores and will end June 1, 1949. The Dean is Willard C. Rappleye, M.D.

Cornell University Medical College, 1300 York Avenue.—Organized in 1898. Coeducational since organization. First year teaching was given formerly to approximately one third of the class at Ithaca but in 1938 this division was discontinued and all instruction is now in New York City. All students admitted are from approved colleges for premedical training. The requirement for admission is three years of college work. The fees average \$700 per year. The registration for 1947-1948 was 315; graduates 78. The last session began for senior students March 31, 1947 and ended March 26, 1948. The freshman, sophomore and junior classes began Sept. 24, 1947 and ended June 17, 1948. The next session for seniors begins on July 12, and for the remaining three classes on Sept. 15 and will end June 15, 1949. The Dean is Joseph C. Hinsey, Ph.D.

New York Medical College, Flower and Fifth Avenue Hospitals, 1 East 105th Street.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869; the title New York Homeopathic Medical College and Hospital in 1887; the title New York Homeopathic Medical College and Flower Hospital in 1908; the title New York Medical College and Flower Hospital in 1936; the present title of New York Medical College, Flower and Fifth Avenue Hospitals, June 22, 1938. The first class graduated in 1861. Coeducational since 1919. Three years of college work is the minimum requirement for admission but a degree is preferred. The fees average \$665 per academic year. The registration for 1947-1948 was 446; graduates 119. The last session began Sept. 15, 1947 and ended June 9, 1948. The next session will begin Sept. 20, 1948, and will end June 8, 1949. The President and Dean is J. A. W. Hetrick, M.D.

New York University College of Medicine, 477 First Avenue, Zone 16.—The Medical Department of New York University (then called the University of the City of New York) was organized in 1841 as the University Medical College. In 1898 it united with the Bellevue Hospital Medical College, organized in 1861, under the name of University and Bellevue Hospital Medical College. In 1935 the name was changed to New York University College of Medicine. In 1947 the charter of the University and the statutes were amended, establishing the New York University-Bellevue Medical Center, which includes the College of Medicine. Coeducational since 1919. Entrance requirements give preference to those who have completed not less than three full years in an approved college of arts and sciences. The fees average \$650 per academic session. The registration for 1947-1948 was 487; graduates 132. The last session began Sept. 22, 1947, and ended May 22, 1948 for freshmen, sophomores and seniors, and June 12, 1948 for juniors. The next session for all classes will begin Sept. 20, 1948, and will end May 27, 1949 for freshmen and sophomores, June 17, 1949 for juniors, and May 21, 1949 for seniors. The Dean is Currier McEwen, M.D.

Rochester

University of Rochester School of Medicine and Dentistry, 260 Crittendon Boulevard, Zone 7.—Organized in 1925 as the Medical Department of the University of Rochester. Coeducational since organization. Three years of collegiate work are required for admission. The fees are \$600 per academic year. The registration for 1947-1948 was 267; graduates 66. The last session for freshmen, sophomores and juniors began Sept. 22, 1947 and ended June 19, 1948; the senior session began March 17, 1947 and ended March 27, 1948. The next session will begin on Sept. 20, 1948 and will end on June 18, 1949. The Dean is George H. Whipple, M.D.

Syracuse

Syracuse University College of Medicine, 766 Irving Avenue, Zone 10.—Organized in 1872, when the Geneva Medical College, chartered in 1834, was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875, when a compulsory three year graded course was established. The first class graduated in 1873 and a class graduated each subsequent year. In 1884 the amalgamation with the university was made complete. Course

extended to four years in 1896. Coeducational since organization. Three years of a recognized college course are required for admission. The fees average \$800 per academic year. The registration for 1947-1948 was 190; graduates 51. The last session began Sept. 5, 1947 and ended June 14, 1948. The next session for all classes will begin approximately Sept. 7, 1948 and will end June 13, 1949. The Dean is H. G. Welskotten, M.D.

NORTH CAROLINA

Durham

Duke University School of Medicine.—Organized in 1930. The first class was admitted Oct. 1, 1930. Coeducational. The premedical requirement is three years of college work. The academic year consists of two semesters in the first year and three quarters each in the sophomore, junior and senior years. There is no summer quarter between the first and second year, but in the two clinical years the subjects of the autumn, winter and spring terms are repeated in the summer quarter. An accelerated program was adopted July 6, 1942 and starting with the summer quarter of 1946 this accelerated schedule became optional; the students may take the two semesters of their first year, and three quarters in each of their subsequent years, and receive their certificates in four calendar years, or if they receive permission from the Curriculum Committee they may at the end of their second year take the clinical quarters given during the summers and receive their certificates in three and one quarter calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. Active duty with the Army, Navy or Public Health Service can replace the second year. The fees are \$750 for three quarters. The registration for 1947-1948 was 270; graduates 66. During 1948 the quarters begin January 5, March 30, July 5, October 4 and end March 20, June 12, Sept. 18 and Dec. 18. The next freshman class will be enrolled Oct. 4, 1948 and will end June 11, 1949. The Dean is Wilburt C. Davison, M.D.

Winston-Salem

Bowman Gray School of Medicine of Wake Forest College, Zone 7.—Organized in 1902 at Wake Forest as a school offering only the first two years of the curriculum. In 1941 the school was moved to Winston-Salem and expanded to a complete four year medical school under its present name. Coeducational. Ninety semester hours of college work are required for admission. Clinical departments operate four quarters in the year; however, the plan of operation makes it possible for students to be out of school during one quarter of each of the clinical years for research, for study elsewhere, or for earning money to help defray the expenses of their education. Tuition averages \$514 per school year. The registration for 1947-1948 was 184; graduates 48. The last session for the freshman class began Sept. 29, 1947, sophomores Sept. 29, 1947, juniors and seniors March 24, 1947, and ended for freshmen and sophomores June 12, 1948, for juniors March 20, 1948, and for seniors Dec. 13, 1947. The present senior class began March 29, 1948, and will end Dec. 18, 1948. The next freshman and sophomore classes will begin Oct. 3, 1948 and will end June 11, 1949. The junior session began July 12, 1948 and will end June 11, 1949. The Dean is C. C. Carpenter, M.D.

OHIO

Cincinnati

University of Cincinnati College of Medicine, Eden and Bethesda Avenues.—Organized in 1909 by the union of the Medical College of Ohio (founded in 1819) with the Miami Medical College (founded in 1832). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a similar agreement, March 2, 1909, the Miami Medical College also merged with the University when the title of Ohio-Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Coeducational since organization. Three years of collegiate work are required for admission. Liberal arts students of the University of Cincinnati may enroll for the seven year combined liberal arts and medical program. The B.S. degree is granted on the joint recommendation of the faculties of the College of Liberal Arts and Medicine at the end of the first medical year. Tuition is as follows: for legal residents of Cincinnati \$325 a year plus breakage fees (\$75 additional for those not legal residents). The registration for 1947-1948 was 321; graduates 76. The last session for freshmen, sophomores, and juniors began Sept. 19, 1947 and ended May 29, 1948. The session for seniors began Feb. 3, 1947 and ended Feb. 7, 1948. The next session for all classes will begin Sept. 24, 1948, and will end June 4, 1949. The Dean is Stanley Dorst, M.D.

Cleveland

Western Reserve University School of Medicine, 2109 Adelbert Road, Zone 6.—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College. The first class graduated in 1844. The school assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. Students are required to have three years of college work for admission. The fees average \$612 per academic year. The registration for 1947-1948 was 312; graduates 77. The last session began Sept. 17, 1947 and ended June 5, 1948. The next session will begin Sept. 15, 1948, for freshmen, sophomores and juniors and will end June 4, 1949; the senior session will begin Aug. 30, 1948 and will end June 15, 1949. The Dean is Joseph T. Wearn, M.D.

Columbus

Ohio State University College of Medicine, Nell and Eleventh Avenues, Zone 10.—Organized in 1907 as the Starling-Ohio Medical College by the union of Starling Medical College (organized in 1847 by charter granted by the State Legislature changing the name from Willoughby Medical College, which was chartered March 3, 1834) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. Coeducational since organization. Three years of collegiate work are required for admission. Tuition fees average \$180 per academic year and \$225 additional for nonresidents. The registration for 1947-48 was 317; graduates 72. The last session for freshman, sophomore and juniors began on Sept. 30, 1947 and ended June 11, 1948; for seniors March 25, 1947 to March 19, 1948. The present session begins Sept. 28, 1948, and ends June 10, 1949. The last accelerated group will be graduated December 17, 1948. The Dean is Charles A. Doan, M.D.

OKLAHOMA

Oklahoma City

University of Oklahoma School of Medicine, 800 North East Thirteenth Street, Zone 4.—Organized in 1900. Until 1910 gave only the first two years of the medical course at Norman, Oklahoma, after which a clinical department was established at Oklahoma City through consolidation with the Medical School of Epworth University. The first class graduated in 1911. Coeducational since organization. A new medical school building and a second teaching hospital became available in 1928, and since September of that year the entire four year course has been given in Oklahoma City. Prerequisites for admission are three years—90 semester hours. The fees for residents of Oklahoma are \$350; nonresidents, \$700. The registration for 1947-48 was 259; graduates 62. The last session began Sept. 15, 1947 and ended May 31, 1948. The next session will begin Sept. 20, 1948 and will end June 6, 1949. The Dean is Mark R. Everett, Ph.D.

OREGON

Portland

University of Oregon Medical School, Marquam Hill, Zone 1.—Organized in 1887. The first class graduated in 1888, and a class graduated each subsequent year except 1898. The Willamette University Medical Department was merged in 1913. Coeducational since organization. Entrance requirement is three years of collegiate work. The total fees are, respectively, \$388.50, \$388.50, \$383.50 and \$390 for residents of Oregon and \$150 a year additional for nonresidents. The registration for 1947-1948 was 270; graduates 65. The last session began Sept. 30, 1947 and ended June 18, 1948. The next session will begin Sept. 29, 1948 and will end June 17, 1949. The Dean is D. W. E. Baird, M.D.

PENNSYLVANIA

Philadelphia

Hahnemann Medical College and Hospital of Philadelphia, 235 North Fifteenth Street, Zone 2.—Organized in 1848 as The Homeopathic Medical College of Pennsylvania. In 1869, it and a corporation known from 1833 to 1867 as The Washington Medical College of Philadelphia and thereafter as The Hahnemann Medical College of Philadelphia were merged under the latter title. Assumed present title in 1885. The first class graduated in 1849. Coeducational beginning with 1941-1942 session. Three years of collegiate work in an approved college of arts and sciences are required for admission. Fees are respectively \$655, \$650, \$650, \$675. The registration for 1947-1948 was 405; graduates 112. The last session began for seniors April 11, 1947 and ended March 18, 1948. The last session for juniors began Sept. 29, 1947 and ended June 5, 1948. The last session for sophomores began Sept. 29, 1947 and ended June 19, 1948. The last session for freshmen began Sept. 22, 1947 and ended June 12, 1948. The next session for freshmen will begin Sept. 20, 1948 and will end May 28, 1949, other classes will begin Sept. 27, 1948 and will end for seniors June 16, 1949, for juniors June 11, 1949, for sophomores June 4, 1949. The Dean is Charles L. Brown, M.D.

Jefferson Medical College of Philadelphia, 1025 Walnut Street.—Organized in 1825 as the Medical Department of Jefferson College, Canonsburg, Pa. It was chartered with its present title in 1838. Classes have been graduated annually beginning in 1826. In 1838 a separate university charter was granted without change of title, since which time it has continued under the direction of its board of trustees. For the class entering in 1949 the minimum entrance requirement will be three years of college work. The tuition fee is \$700 a year. The registration for 1947-1948 was 621; graduates 148. The last session began for all classes on Sept. 11, 1947 and ended for juniors and seniors on May 31, 1948; for freshman on June 7, 1948, for sophomores June 10, 1948. Graduation was on June 4, 1948. The next session will begin for all classes on Sept. 11, 1948 and will end in June 1948. The Dean is William H. Perkins, M.D.

Temple University School of Medicine, 3400 North Broad Street, Zone 40.—Organized in 1901. The first class graduated in 1904. Coeducational since organization. Three years of collegiate work are required for admission. The fees average \$710 per academic year. The registration for 1947-1948 was 459; graduates 124. The last session began Sept. 22, 1947 and ended June 17, 1948. The next session will begin Sept. 20, 1948 and will end June 16, 1949. The Dean is William N. Parkinson, M.D.

University of Pennsylvania School of Medicine. Thirty-Sixth and Pine Streets.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772 and 1775-1779, inclusive. The original title was the Department of Medicine, College of Philadelphia. The present title was adopted in 1909. It granted the first medical diploma issued in America. In 1916, it took over the Medical-Chirurgical College of Philadelphia to develop it as a graduate school. Coeducational since 1914. Three years of collegiate work are required for admission. The tuition fee is \$700, with a deposit fee of \$15, a general fee including student health of \$15 and a matriculation fee of \$5. The registration for 1917-1918 was 179; graduates 127. The last session for seniors began April 7, 1917 and ended March 6, 1918. The last session for freshmen, sophomores and juniors began Sept. 22, 1917 and ended June 9, 1918. The next session will begin Sept. 27, 1918 and will end June 15, 1919. The Dean is John McK. Mitchell, M.D.

Women's Medical College of Pennsylvania, Henry Avenue and Abbottsford Road, Zone 29.—Organized in 1850. Classes were graduated in 1852 and in all subsequent years except 1862. At least three years of collegiate work are required for admission and candidates with a degree are given preference. The curriculum covers four years of eight and one-half to nine months each. Total fees are \$675 yearly. The registration for 1917-1918 was 158; graduates 35. The last session began Sept. 11, 1917 and ended June 4, 1918. The next session will begin Sept. 16, 1918 and will end June 30, 1919. The Dean is Marlon Fay, Ph.D.

Pittsburgh

University of Pittsburgh School of Medicine, 3911 O'Hara Street.—Organized in 1886, as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. Coeducation since 1899. Entrance requirements are two years of collegiate work. The total fees are \$500 each year. The registration for 1917-1918 was 303; graduates 15. The last session for seniors began April 7, 1917 and ended March 27, 1918. The last freshman, sophomore and junior classes began Sept. 29, 1917 and ended June 26, 1918. The next session will begin on Sept. 13, 1918 for all classes and will end June 8, 1919. The Dean is William S. McElroy, M.D.

SOUTH CAROLINA

Charleston

Medical College of the State of South Carolina, 16 Lucas Street, Zone 16.—Organized 1823 as the Medical College of South Carolina. The first class graduated in 1825. In 1832 a medical college bearing the present title was chartered and the two schools continued as separate institutions until they merged in 1838. Classes were graduated in all years except 1862 to 1865, inclusive. Coeducational from 1895 to 1912, when privileges for women were withdrawn, being restored in 1917. At least three years of collegiate work are required for admission. The total fees average \$125 each year for residents of South Carolina and \$625 for nonresidents of the state. The registration for 1917-1918 was 212; graduates 53. The last session began Sept. 25, 1917 and ended June 3, 1918. The next session will begin Sept. 23, 1918 and will end June 2, 1919. The Dean is Kenneth M. Lynch, M.D.

TENNESSEE

Memphis

University of Tennessee College of Medicine, 874 Union Avenue, Zone 3.—Organized in 1876, at Nashville as Nashville Medical College. First class graduated in 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee in 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees of the University of Nashville by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it united with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Lincoln Memorial University Medical Department was merged in 1914. Coeducational since 1911. Two years of collegiate work are required for admission. The B.S. degree is conferred on students completing the science-medical curriculum of the University. The fees are \$175 quarterly. For residents of the state the charge is reduced \$50 each quarter. The registration for 1917-1918 was 511; graduates 99. During the next academic year the quarters begin September, January, March and July. The Dean is O. W. Hyman, Ph.D.

Nashville

Meharry Medical College, Eighteenth Avenue North and Meharry Boulevard, Zone 8 (For Negro Youth).—Organized in 1876 as the Meharry Medical Department of Central Tennessee College, which became Walden University in 1900. First class graduated in 1877. Obtained new charter independent of Walden University in 1915. Coeducational since 1876. Two years of college work in a school of liberal arts are required for admission. Tuition and fees are: first year \$410, second year \$400, third year \$390 and fourth year \$400. The curriculum covers four academic

years of thirty-six weeks each. In September 1912, Meharry Medical College instituted the quarter system. The registration for 1917-1918 was 231; graduates 58. The last session began on Sept. 29, 1917 and ended on June 19, 1918. The next session begins on Sept. 27, 1918 and will end on June 18, 1919. The Director of Medical Education is Murray C. Brown, M.D.; the Dean is Michael J. Bent, M.D.

Vanderbilt University School of Medicine, Twenty-First Avenue South at Edgehill, Zone 4.—This school was founded in 1874. The first class graduated in 1875. Coeducational since 1925. For matriculation, students must be graduates of collegiate institutions of recognized standing or seniors in absentia, who will receive the bachelor degree from their college after having completed successfully one year of work in the school of medicine. The course covers four academic years of nearly nine months each. The fees average \$615 per academic year. The registration for 1917-1918 was 207; graduates 54. The last session began Sept. 22, 1917 and ended June 7, 1918. The next session will begin on Sept. 27, 1918 and will end June 6, 1919. The Dean is Ernest W. Goodpasture, M.D.

TEXAS

Dallas

Southwestern Medical College, 2211 Oak Lawn.—Organized in 1943. The first class graduated March 20, 1944. Coeducational since organization. The medical college is operated on the regular program offering three terms of twelve weeks each per academic year. Tuition for an academic year is \$575. Hospitalization charges are not included in this fee. Ninety semester hours are required for admission. Registration for 1917-1918 was 224; graduates 50. The last session began Sept. 8, 1917 and ended for freshmen and seniors on June 7, 1918 and for sophomores and juniors on June 26, 1918. The next session will begin Sept. 7, 1918 and end June 6, 1919. The Dean is W. Lee Hart, M.D.

Galveston

University of Texas School of Medicine, 912 Avenue B.—Organized in 1891. The first class graduated in 1892. Coeducational since organization. Ninety semester hours are required for admission to the freshman class matriculating in September 1948, but students are urged to complete the baccalaureate degree if possible prior to matriculation. The fees average \$113 per academic year, including health fees for medical care and hospitalization. The registration for 1917-1918 was 317. Graduates on Feb. 13, 1918 were 80. The last session began on Sept. 15, 1917 for the freshman, sophomore, and junior classes and ended on June 12, 1918. The senior class for the last session began on Feb. 10, 1917 and ended Feb. 13, 1918. The next freshman class will matriculate on Sept. 20, 1918, and the sophomore, junior, and senior classes will matriculate on Sept. 27, and all classes will end June 11, 1919. The Vice President is Chauncey D. Leake, Ph.D., and D. Bailey Calvin, Ph.D., is Dean of Student and Curricular Affairs.

Houston

Baylor University College of Medicine, Texas Medical Center.—Organized in 1900 at Dallas as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University. It acquired the charter of Dallas Medical College in 1904. The school was moved to Houston in 1943. Coeducational since organization. The first class graduated in 1903. Entrance requirements are 90 semester hours of collegiate work. The course covers four years of eight months each. The fees are respectively \$556, \$546, \$531, \$556. The registration for 1917-1918 was 293; graduates 61. The last session began Oct. 6, 1917 and ended June 14, 1918. The next session will begin Oct. 4, 1918 and will end June 13, 1919. The Dean is W. H. Moursund, M.D.

UTAH

Salt Lake City

University of Utah College of Medicine.—Organized in 1906. Coeducational since organization. Four year curriculum established March 1943. Three years of collegiate work are required for admission. The University of Utah has accepted in principle the policy of acceleration by graduating a class in three calendar years (4 academic years), but will admit only one class annually. The next freshman class will be admitted in June, 1949. All subsequent freshman classes will begin in June of each year. Classes are scheduled during four academic quarters (11-12 wks.) each calendar year. An entering first year student may be graduated in 12 academic quarters (3 calendar years) after date of admission; attendance during the summer quarter being required. Applications for admission (complete) must be submitted 9 months prior to opening date. The fees for each quarter average \$148; there is a nonresident fee of \$55 each year. The registration for 1917-1918 was 178; graduates 36. The last session began for freshmen June 16, 1917 and ended March 19, 1918. The present session for freshmen began June 14, 1918 and will end March, 1919. The present session for sophomores began March 27, 1918 and will end Dec., 1918. The present session for juniors and seniors began Jan., 1918 and will end Aug. 28, 1918. The Dean is Richard H. Young, M.D.

VERMONT

Burlington

University of Vermont College of Medicine, Pearl Street, College Park. Organized with complete course in 1822. Classes graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1833 and classes were graduated in 1854 and in all subsequent years. Coeducational since 1920. Three years of college work are required for admission. For residents of Vermont the tuition fee averages \$500 per session. Nonresidents are charged an additional \$150 each session. A \$25 fee is charged for the doctor's degree. Registration for 1947-1948 was 153; graduates 40. The last session for freshmen, sophomores and juniors began Sept. 20, 1947 and ended June 21, 1948. The last senior class began July 13, 1947 and graduated June 21, 1948. The next senior class will begin July 3, 1948; the next freshman, sophomore and junior classes will begin Sept. 18, 1948 and all classes will end June 20, 1949. The Dean is William Eustis Brown, M.D.

VIRGINIA

Charlottesville

University of Virginia Department of Medicine.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. Coeducational since the session of 1920-1921. Three years of college work are required for admission. For residents of Virginia the average tuition fee is \$428 per academic year; for nonresidents, \$578. The registration for 1947-1948 was 250; graduates 59. The last session began Sept. 15, 1947 and ended June 14, 1948. The next session will begin Sept. 14, 1948 and will end June 13, 1949. The Dean is Harvey E. Jordan, Ph.D.

Richmond

Medical College of Virginia, Twelfth and Marshall Streets.—Organized in 1838 as the Medical Department of Hampden-Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. In 1914 the North Carolina Medical College was merged. Coeducational since 1918. Classes were graduated in 1839 and in all subsequent years. Three years of collegiate work, as a minimum, are required for admission. Preference, however, is given

to applicants with a baccalaureate degree. Fees average \$510 per academic year. Nonresidents are charged an additional \$200 each year. The registration for 1947-1948 was 314; graduates 85. The last session began Sept. 15, 1947 for second, third and fourth year classes and ended June 8, 1948. The last session for the first year class began Sept. 10, 1947 and ended June 8, 1948. The subsequent session will begin Sept. 9, 1948 for the first year class and Sept. 13, 1948 for the second, third and fourth year classes and will end June 7, 1949. The Dean is Harvey B. Haag, M.D. The Associate Dean and Chairman of the Admissions Committee is Mr. George W. Bakeman.

WISCONSIN

Madison

University of Wisconsin Medical School, 418 North Randall Avenue, Zone 6.—Organized 1907. Gave only the first two years of the medical course until 1925, when the clinical years were added. Coeducational since organization. Fees for the first, second and third years are \$280, for the fourth year \$190 per academic year for residents. An additional fee of \$200 per year is charged nonresidents. Registration for 1947-1948 was 278; a class of 59 was graduated June 19, 1948. The last session for freshman, sophomore and junior students began Sept. 9, 1947 and ended June 19, 1948. The last session for seniors began June 9, 1947 and ended June 19, 1948. The present senior class began June 28, 1948 and will graduate June 18, 1949. Freshman, sophomore and junior classes will begin Sept. 20, 1948 and will end June 18, 1949. The Dean is William S. Middleton, M.D.

Milwaukee

Marquette University School of Medicine, 561 North Fifteenth Street.—Organized in December 1912 by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. Three years of collegiate work are required for admission. The fees are \$600 per academic year. The registration for the 1947-1948 session was 350; graduates 82. The last session began Sept. 29, 1947 and ended June 5, 1948. The next session for freshman, sophomore and junior students will begin Sept. 27, 1948 and will end May 28, 1949. The present session for seniors began July 5, 1948 and will end June 12, 1949. The Dean is John S. Hirschboeck, M.D.

APPROVED MEDICAL SCHOOLS IN CANADA

Alberta

University of Alberta Faculty of Medicine, Edmonton.—Organized in 1913. Coeducational since organization. Has given complete medical course since 1924. New course—three years premedical, four years of medicine—offered with the session 1947-1948. Tuition for the four years is \$350 per session. The registration for 1947-1948 was 171; graduates, two classes, old five year—32, new four year—44. The last session began Sept. 16, 1947 and ended June 15, 1948. The next regular session will begin Sept. 7, 1948 and end June 15, 1949. The Dean is John W. Scott, M.D.

Manitoba

University of Manitoba Faculty of Medicine, Bannatyne Avenue, Winnipeg.—Organized in 1883 as Manitoba Medical College. First class graduated in 1886, and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. Matriculation requirements include two years of collegiate work in the faculty of arts and sciences of a recognized university. This will be increased to three years with the session 1949-1950. The course extends over four years of eight months each and a hospital internship. The fees average \$396 yearly. The registration for 1947-1948 was 280; graduates 62. The last session began Sept. 15, 1947 and ended May 18, 1948. The next session will begin on Sept. 10, 1948 and will end on May 15, 1949. The Dean is A. T. Mathers, M.D.

Nova Scotia

Dalhousie University Faculty of Medicine, Morris Street, Halifax.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the *Governors of Dalhousie University and the Corporation of the Halifax Medical College*, the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. Requires for matriculation two years of arts. The regular medical course covers four years and a hospital internship of one year approved by the medical faculty. The fees average \$331 yearly; \$250 additional registration fee payable by students outside the British Empire. The registration for 1947-1948 was 204; graduates 31. The next session for all classes will begin Sept. 14, 1948 and will end May 17, 1949. The Dean is H. G. Grant, M.D.

Ontario

Queen's University Faculty of Medicine, Kingston.—Organized in 1829. First class graduated in 1855 and a class graduated each subsequent year. Fees for the first year amount to \$342.50 and for each of the other five years \$358.50. The course consists of five sessions of 30 teaching weeks, and a sixth year spent in a hospital designated by the University. The degrees of M.D., C.M. are not awarded until the end of the sixth year. Freshmen will be admitted annually. Registration for 1947-1948 was 270. The last session began Sept. 22, 1947 and ended May 15, 1948. The next session will begin Sept. 27, 1948 and will end May 14, 1949. The last convocation was held on June 19, 1947. As a result of the discontinuance of the accelerated medical course there will be no graduating class until June 1949. The Dean is G. Spencer Melvin, M.D.

University of Western Ontario Faculty of Medicine, 346 South Street, London.—Organized in 1881 as the Western University Faculty of Medicine. First class graduated in 1883 and a class graduated each subsequent year. Present title in 1923. The Faculty of Medicine has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The normal course of study covers two honour college years of nine months each and four years of ten months each in the Faculty of Medicine. The total fees to residents of Canada for the last four years, respectively, are \$390, \$390, \$390, \$398; nonresidents are charged \$700, \$700, \$700, \$708 for each of the last four years. The registration for 1947-1948 was 217; graduates 40. The last session began Sept. 8, 1947 and ended June 11, 1948. The next session begins Sept. 13, 1948 and ends May 21, 1949. The Dean is J. B. Collip, M.D.

University of Toronto Faculty of Medicine, Toronto 3.—Organized in 1843 as the Medical Faculty of King's College, Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University Medical Department and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The degree of M.D. is conferred after 4 years in the study of medicine. Admission to the medical course is gained following honour matriculation and after two years in the study of premedical requisites in the University of Toronto. A certain number are admitted each year to the first medical year who hold Arts degrees from recognized universities and who have covered the necessary work in the humanities and sciences. The B.Sc. (Med.) degree may be conferred for special work or investigation as a graduate degree, or under certain circumstances for an extra year's work as an undergraduate. The registration for 1947-1948 in the medical and premedical years was 945; graduates 129. The last class began Sept. 23, 1947 and ended May 1,

1948. The next session for first and second premedical years will begin on Sept. 21, 1948 and for first, second, third and fourth medical years on Sept. 28, 1948. The session for premedical years will end on April 30 and for medical years on May 14, 1949. Students will graduate annually in June. The Dean is J. A. MacFarlane, M.B.

Quebec

McGill University Faculty of Medicine. 3610 University Street, Montreal.—Founded in 1823 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-1839, owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College. Coeducational since 1917. Four years of collegiate work are required for admission. The total fees for each of the four medical years are \$461. The registration for 1947-1948 was 377; graduates 119. The last session began Sept. 3, 1947 and ended June 1, 1948. The next session will begin Sept. 7, 1948 and will end June 4, 1949. The Dean is Frederick Smith, M.D.

University of Montreal Faculty of Medicine. 2900 Mount Royal Boulevard, Montreal.—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891, by Act of Parliament, the Medical Faculty of

Laval University (organized in 1878) was absorbed. Present name by Act of Parliament in 1920. A class was graduated in 1843 and each subsequent year. Coeducational since 1925. The requirements for admission are: First, a B.A. degree (or its equivalent); second, one year premedical in the faculty of pure sciences (or an entrance examination on the premedical subjects). An internship is required for graduation. The fees average \$285 yearly. The registration for 1947-1948 was 382; graduates 100. The last session began Sept. 15, 1947 and ended May 8, 1948. The next session will begin Sept. 15, 1948 and will end May 14, 1949. The Dean is Edmond Dubé, M.D.

Laval University Faculty of Medicine, Quebec.—The Quebec School of Medicine, organized in 1818, became in 1852 the Laval University Faculty of Medicine; first class graduated in 1855, and a class graduated each subsequent year. The fees for each of the medical years average \$226 for residents of Canada. Nonresidents are charged an extra fee of \$200 each year. The premedical requirement is a B.A. degree or its equivalent. The registration for 1947-1948 was 551; graduates 72. The last session began Sept. 8, 1947 and ended June 3, 1948. The next session will begin Sept. 15, 1948 and will end June 1, 1949. The Dean is Charles Vézina, M.D.

APPROVED SCHOOLS OF THE BASIC MEDICAL SCIENCES IN THE UNITED STATES

MISSISSIPPI

University

University of Mississippi School of Medicine.—Organized in 1903. Coeducational since organization. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. Entrance requirement is three years of collegiate work or ninety semester hours of credit. Fees average \$381 annually. There is a nonresident fee of \$200. The school operates on an accelerated program by accepting two freshman classes each session. The last session began Sept. 15, 1947 and ended May 29, 1948. Additional freshman class admitted Feb. 2, 1948 and will complete the year Sept. 25, 1948. The sophomore session began July 7, 1947 and ended March 13, 1948. An additional sophomore session began Sept. 27, 1947 and ended July 10, 1948. The next freshman class will begin Sept. 20, 1948 and will end May 28, 1949; the next sophomore class will begin Nov. 1, 1948 and will end July 9, 1949. The Dean is David S. Pankratz, M.D.

MISSOURI

Columbia

University of Missouri School of Medicine.—Organized at St. Louis in 1845; was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. The entrance requirements are 90 semester hours of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. Total fees for the first year are \$206, for the second \$300. The registration for 1947-1948 was 73. The last session began Sept. 16, 1947 and ended June 4, 1948. The next session begins Sept. 17, 1948 and will end June 7, 1949. The Dean is Trawick H. Stubbs, M.D.

NEW HAMPSHIRE

Hanover

Dartmouth Medical School.—Organized by Dr. Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the Trustees of Dartmouth College. Courses of the third and fourth years were discontinued in 1914. Three years of college work and candidacy for the bachelor's degree are required for admission. Candidates for the A.B. degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year. The tuition is \$600 for each year. The registration for 1947-1948 was 46. The last session began on Oct. 3, 1947 and ended June 13, 1948. The next session will begin Sept. 27, 1948 and will end June 12, 1949. The Dean is Rolf C. Syvertsen, M.D.

NORTH CAROLINA

Chapel Hill

University of North Carolina School of Medicine.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department in Raleigh. The first class was graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. Coeducational since 1914. Three years of college work are normally required for admission. Certificates are awarded on the completion of two years' work in medicine. The fees are \$375 for the first year and \$385 for the second year for residents; for nonresidents an additional fee of \$100 per year. The registration for 1947-1948 was 100. The North Carolina Legislature of 1947 appropriated funds for the expansion of the school to the full four years. The full program will probably not get under way for three to four years. The last session began Sept. 23, 1947, and ended June 5, 1948. The next session will begin Sept. 20, 1948, and end June 4, 1949. The Dean is W. Reece Berryhill, M.D.

NORTH DAKOTA

Grand Forks

University of North Dakota School of Medicine.—Organized in 1907. Offers only the first two years of the medical course. Coeducational since organization. Three years work in a college of liberal arts are required for admission. The B.S. degree in combined arts-medical course is conferred at the end of the second year. The fees are \$150 each year for resident students and \$228 for nonresidents. The registration, academic year 1947-1948, was 51. The last session began Sept. 25, 1947 and ended June 12, 1948. The next session will begin Sept. 20, 1948 and will end June 10, 1949. The Dean is W. F. Potter, M.D.

SOUTH DAKOTA

Vermillion

University of South Dakota School of Medical Sciences.—Organized in 1907 as the University of South Dakota School of Medicine. Present title in 1937. Coeducational since organization. Offers only the first two years of the medical course. Three years work in a college of liberal arts are required for admission. Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to an A.B. degree. The B.S. degree is conferred at the end of the second year on those students who do not hold a combination (Arts and Sciences and Medicine Course) A.B. degree. The tuition is \$260 for first year residents and \$280 for second year residents; \$470 for first year nonresidents and \$490 for second year nonresidents. The registration for 1947-1948 was 54. The last session began Sept. 8, 1947 and ended May 29, 1948. The next session will begin Sept. 6, 1948 and will end May 30, 1949. The Dean is Donald Slaughter, M.D.

WEST VIRGINIA

Morgantown

West Virginia University School of Medicine.—Organized in 1902. Gives the first two years of the medical course, but agreement has been made for the transfer of 20 students each year to the Medical College of Virginia. Coeducational since organization. Entrance requirements are three years of collegiate work. The B.S. degree is conferred at the end of the second year. Fees for residents of the state are, respectively, \$254 and \$264; nonresidents, \$150 additional each year. The registration for 1947-1948 was 55. The last session began Sept. 15, 1947 and ended May 31, 1948. The next session will begin Sept. 13, 1948 and will end May 30, 1949. The Dean is Edward J. Van Liere, M.D.

APPROVED SCHOOL OF THE BASIC MEDICAL SCIENCES IN CANADA

Saskatchewan

University of Saskatchewan School of Medical Science, Saskatoon. Organized in 1926. Coeducational. Offers the first two years of the medical course. Two years of collegiate work are required for admission. The B.A. degree is conferred at the end of the second year. The fees are \$298. The registration for 1947-1948 was 55. The last session for freshmen began Sept. 22, 1947 and ended June 26, 1948. The next session will begin Sept. 20, 1948 and will end June 21, 1949. The Dean is W. S. Lindsay, M.B.

APPROVED EXAMINING BOARDS IN MEDICAL SPECIALTIES

An American board in a specialty is organized (a) to assist in improving the quality of graduate education in that field, (b) to establish minimum educational and training standards in the specialty, (c) to determine whether candidates have received adequate preparation, (d) to provide comprehensive examinations to determine the ability and fitness of such candidates and (e) to certify to the competence of those physicians who meet these requirements.

Sixteen boards in the specialties have been organized and are approved by the Council on Medical Education and Hospitals of the American Medical Association, and as of March 1, 1948, 31,498 physicians have been certified. The following table lists the approved

TABLE 22.—Approved Examining Boards in Medical Specialties

specialty boards, the date of organization, the number of certificates awarded prior to March 1, 1947 and the number certified to March 1, 1948. Likewise shown in these two categories are the numbers certified in the subspecialties. A third column in this table includes the total number of living certified specialists for the boards that were able to supply such figures. On March 1, 1947 there were 28,496 physicians certified by the fifteen boards in operation. During 1947 the American Board of Physical Medicine was approved and certified 86 physicians. Altogether, 3,002 physicians were certified from March 1, 1947 to March 1, 1948. Up to this latter date a total of 31,498 physicians

have been certified by sixteen boards. Up to March 1, 1947, 898 certificates in subspecialties were awarded, and during the ensuing year 84, bringing the total in the subspecialties to 982 as of March 1, 1948.

Several of the boards have made changes in their requirements. For the guidance of candidates desiring to qualify for certification, the requirements of the boards are reprinted below verbatim from their published announcements.

AMERICAN BOARD OF ANESTHESIOLOGY

CURTISS B. HICKCOX, Philadelphia.
JOHN S. LUNDY, Rochester, Minn.
CHARLES F. McCUSKEY, Los Angeles.
E. A. ROVENSTINE, New York.
HENRY S. RUTH, Philadelphia.
MEYER SAKLAD, Providence, R. I.
RALPH M. TOVELL, Hartford, Conn.
ROLLAND J. WHITACRE, Cleveland.
JOHN W. WINTER, San Antonio, Texas.
PAUL M. WOOD, Secretary-Treasurer, 745 Fifth Avenue, New York 22.

QUALIFICATIONS FOR ELIGIBILITY TO CERTIFICATION

A. *General*.—1. An applicant's moral and ethical standing in the profession must be satisfactory to the entire board. The board must be assured that the applicant is engaged in the practice of anesthesiology as a specialty and that he intends to continue to be so engaged.

2. Membership is required in the American Medical Association or membership in such other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Membership in other societies shall not be required.

3. Practice must have been limited to anesthesiology for five calendar years, of which at least two must have been devoted to special training.

4. In exceptional instances the board may, in its discretion, accept for examination candidates who have met all the preliminary requirements and have clearly demonstrated their identity as anesthetists over a period of years, but whose formal training does not comply with the full requirements.

B. *Professional Standing*.—1. An applicant must be a graduate of a medical school in the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association, or a diplomate of the National Board of Medical Examiners.

2. Satisfactory evidence must be supplied of completion of an internship of not less than one year in a hospital approved by the same Council, or its equivalent in the opinion of the board.

3. An applicant must establish in a manner satisfactory to the Board of Anesthesiology: that he is a physician duly licensed by law to practice medicine; that he is of high ethical and professional standing, and that he has received adequate training in Anesthesiology.

C. *Special Training and Practice*.—1. Before certification the candidate must have had an active experience limited to anesthesiology of not less than five calendar years (including period of training).

2. The board requires the inclusion of at least two years of carefully supervised instruction in the clinical phases of anesthesiology in hospital clinics, dispensaries and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the teaching and practice of anesthesiology. In addition, instruction in anatomy, physiology, pharmacology, biochemistry and other basic sciences which are necessary to the proper understanding of the problems involved in the specialty of anesthesiology is required.

EXAMINATIONS

The qualifying examination will be divided into Part I, written; Part II, oral, and Part III, practical

PART I

1. An applicant to be eligible for Part I must meet all supervised training requirements, and his credentials must be approved by the board.

2. Part I may be given simultaneously in several places, which the board may deem suitable for the purpose, on the third Friday of each January.¹

PART II

1. In order to be eligible for Part II, a candidate must have successfully passed Part I and must be a member of the American Medical Association.

2. Part II examinations will be held during the third week in October at a place announced in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. Later, however, as the demand grows, it may be necessary to establish additional dates when this part may be held.²

PART III

1. The examiners will observe the work of the candidates in their own or similar operating room surroundings, their relations to other staff members, and investigate their professional standing.

Conduct of Examination.—Carefully conducted and thorough examinations will be required of candidates. The aim will be to avoid unduly exacting standards above present facilities for study and practice in anesthesiology and, on the other hand, to prevent laxity, which would nullify the main purpose of the certification. Thus the type of examination will depend upon a careful review of the work done, years of practice, special courses of study and professional standing of the applicant.

Written examinations will cover such topics as anatomy, biochemistry, physiology, pharmacology, pathology, physical diagnosis, therapeutics and clinical practice in relation to anesthesiology.

Oral examinations will cover topics in the above list, especially as to their clinical application.

Practical demonstrations will be required of the management of the candidate's clinical practice in his local surroundings. This may include inspection of clinical records, records of departmental activities, library facilities, available apparatus, and demonstrations of application of anesthetic agents, methods and technics included in anesthesiology.

Grades.—A candidate must receive a passing average for each part to be entitled to certification.

A candidate who fails in his examination in Parts I, II or III may be permitted reexamination at yearly intervals for two (2) consecutive examinations in that part without further payment of fee. The board may, however, for sufficient reason, deny a candidate the privilege of reexamination.

Applicants who fail to exercise the examination privilege within three (3) years of the date of becoming eligible for examination are required to file a new application and pay a new application fee.

Fee.—The fee shall be \$100. At least \$25 shall be paid on filing the application (of which sum \$15 will be returned if the candidate is not accepted for examination) and the remainder shall be paid before taking the examinations.

This board is a nonprofit organization. All fees are to be used to extend the existing facilities for training in anesthesiology, after deducting necessary expenses for maintenance of the office, and the conducting of examinations. The board reserves the right to increase the fee when found necessary.

Additional Information.—Every candidate applying for certification must personally appear before the board before being certified.

Application must be made on special blanks to be procured only on written request by the applicant from the secretary of

1. If there are sufficient applicants written examinations may be held on the third Friday of July annually.

2. Oral examinations may be held during the third week of April annually.

The American Board of Anesthesiology. They must be completely and accurately filled out, accompanied by the other required credentials, and filed with the secretary after one year of supervised instruction and at least three months prior to the date of examination.

The secretary cannot make any eligibility rulings. These are made only by the entire board on recommendation of the appropriate committees after reviewing the candidate's formal application. Applications cannot be considered for classification and action by these committees unless accompanied by an application fee of \$25, \$10 of which is not returnable.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY

FRANCIS E. SENEAR, President, Chicago.

J. GARDNER HOPKINS, Vice President, New York.

GEORGE M. LEWIS, Secretary-Treasurer, 66 East 66th Street, New York 21.

FRANK E. CORMIA, Assistant Secretary, New York.

NELSON P. ANDERSON, Los Angeles.

ANTHONY C. CIPOLLARO, New York.

HENRY E. MICHELSON, Minneapolis.

PAUL O'LEARY, Rochester, Minn.

BEDFORD SHIELMIRE, Dallas, Texas.

FRED D. WEIDMAN, Philadelphia.

REQUIREMENTS FOR ELIGIBILITY FOR EXAMINATION

I. GENERAL REQUIREMENTS

1. High ethical and professional standing.

2. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association. The credentials of graduates of foreign schools must be approved by the National Board of Medical Examiners.

3. Satisfactory completion of an internship of not less than one year in a hospital approved by the same Council, or its equivalent in the opinion of the board.

4. A license to practice medicine issued by endorsement of the certificate of the National Board of Medical Examiners or following examination.

5. Membership in the American Medical Association or membership in a similar society recognized as having the same purpose as the American Medical Association.

6. Citizenship in the United States or citizenship—meaning native citizens—in Canada or Cuba.

II. SPECIAL REQUIREMENTS

Applicants for certification of the Board are classed in two groups as follows:

Group A consists of physicians who have limited their practice mainly to dermatology and syphilology for ten or more years, including a period of training satisfactory to the Board. This classification will be abolished after Jan. 1, 1949.

Group B consists of physicians who have completed an approved three year period of training.

In accordance with the program recommended to the various specialty boards by the Advisory Board for Medical Specialties the following minimum requirements of special training for admission to examination have been established:

A period of study, after the internship, of not less than three years. This training may be obtained as resident, fellow or graduate student in clinics, dispensaries, hospitals or laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association and approved by the American Board of Dermatology and Syphilology as competent to provide a satisfactory training in dermatology and syphilology. This period of specialized training shall include:

(a) At least one calendar year in an institution approved for three year training (less one month for vacation).

(b) Graduate training in the basic medical sciences which are necessary for the proper understanding and treatment of the diseases involved in this specialty.

Instruction in the following fundamental subjects as related to the skin is deemed advisable by the board: embryology, histology, chemistry, physiology, bacteriology, mycology, parasitology, pathology, immunology, serology, pharmacology and material medica, and physics of physical therapy.

(c) Carefully supervised clinical and laboratory experience in the specialty.

(d) Annual examinations in the clinical, laboratory and public health aspects of dermatology and syphilology.

PRECEPTORSHIP TRAINING

Candidates may spend one year of their training in the office of a diplomate of the board, who has also been approved as a preceptor by the board. The office training may be divided over two years, with one-half day spent in the office of the preceptor and the other half day in an approved institution. Preceptorship training may be taken during any of the years of training. Time spent with an instructor who has not been approved by the board may count only as experience and not as training. A list of approved preceptors is available in the office of the secretary.

The board assumes the responsibility of determining the standards of knowledge to be acquired, but upon the candidate rests the responsibility of acquiring the knowledge to fill these standards.

PRELIMINARY REGISTRATION, APPLICATION AND FEE

All students beginning their graduate training should file a preliminary registration form with the secretary.

In order that the committee on requirements may appraise carefully the qualifications of candidates, application must be made on a special blank, which may be obtained from the secretary. No application will be considered unless made on the regular application blank. Applications should be filed early in order to obtain full advantage of the sets of histopathologic slides which are available through the Army Medical Museum in Washington. The completed application blank should be sent, at least two months before the date of examination, to the secretary of the board together with the required reprints, photographs and a registration fee of \$25 which will not be refunded under any circumstances. No application will be considered until this fee is received. An examination fee of \$75 is payable when the candidate is notified that his application is acceptable to the board. The fee of \$100 has been carefully computed and is used entirely for administrative purposes. Examiners for the board do not receive any compensation except for actual expenses connected with holding the examinations.

Make checks payable to American Board of Dermatology and Syphilology, Inc.

EXAMINATIONS

Applicants classified in Group B will be required to pass a written examination. This written examination on clinical, basic science and laboratory subjects will be held simultaneously at stated intervals in different parts of the country, approximately two months before the oral examination. Candidates must pass the written examination before being admitted to the oral examination.

Applicants classified either in Group A or in Group B will be required to pass an oral, clinical and laboratory examination. This examination will be conducted in a clinic or hospital ward where individual cases will be discussed with each candidate, as well as various subjects related to the skin such as histopathology, mycology, allergy and physics of physical therapy. The board reserves the right to add to this list other subjects within the field of dermatology and syphilology.

A candidate for a certificate may take both the written and oral examinations at the next regular examination of the board after he has completed three full years of training in the specialty; this provision does not affect the regulations about the issuance of the certificate. (See Certificates.)

Examinations are designed to test the candidate's fitness to practice dermatology and syphilology as a specialty. The board will try especially to ascertain the breadth of his

knowledge in the basic, as well as the clinical aspects of cutaneous medicine, to test his familiarity with the recent literature of dermatology and syphilology and to ascertain his general qualifications as a specialist in this branch of medicine.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instructions for the purpose of overcoming deficiencies in the applicant's knowledge of this specialty.

Except in special circumstances, applicants shall take the examination within the year following the filing of application and the deposit of the fee.

The oral examination may be held near the time and place of the annual meeting of the American Academy of Dermatology and Syphilology. This examination will be held only at the time of regular meetings of the Board.

REEXAMINATIONS

If the candidate fails or is conditioned in an examination he will be admitted to a second examination after one year, and must give sixty days' notice of his intention to appear for reexamination. If a candidate who has failed or has been conditioned does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of \$75 before reexamination.

A candidate who has failed twice must file a new application and pay an additional fee of \$75.

CERTIFICATES

A certificate will not be issued until the candidate has completed at least five years of dermatologic training and experience. The granting of this certificate by the board indicates that the holder of the certificate has had adequate training in dermatology and syphilology and has successfully fulfilled the requirements of the board.

A certificate granted by this board does not of itself confer or purport to confer any degree or legal qualifications, privileges or license to practice dermatology or syphilology. The board does not intend to limit or interfere with the professional activity of any duly licensed physician. Its aim is to improve the standards of practice of dermatology and syphilology by encouraging improvement in the opportunities for and quality of training for specialists in this field of medicine, and to certify as specialists those who voluntarily comply with the requirements of the board.

Certificates will be issued only to physicians in the United States and its possessions, in Canada, and in Cuba.

AMERICAN BOARD OF INTERNAL MEDICINE

HUGH J. MORGAN, Chairman, Nashville, Tenn.

MARION A. BLANKENHORN, Vice Chairman, Cincinnati.

TRUMAN G. SCHNABEL, Secretary-Treasurer, 1704 Pine Street, Philadelphia.

WILLIAM A. WERRELL, Assistant Secretary-Treasurer, 1 West Main Street, Madison 3, Wis.

LEROY H. BRIGGS, San Francisco.

ALEXANDER M. BURGESS, Providence, R. I.

CHESTER M. JONES, Boston.

WALTER L. PALMER, Chicago.

WILLIAM B. PORTER, Richmond, Va.

BURRELL O. RAULSTON, Los Angeles.

ROY W. SCOTT, Cleveland.

VIRGIL P. W. SYDENSTRICKER, Augusta, Ga.

CECIL J. WATSON, Minneapolis.

REQUIREMENTS FOR ADMISSION TO EXAMINATION AND CERTIFICATION

Each applicant for certification by this board must satisfy the qualifications listed below: (I) General Qualifications A, B, C, D; (II) Professional Qualifications A, B, C, D. For exceptions to the requirements C and D under Professional Qualifications see paragraph G.

I. GENERAL QUALIFICATIONS

A. All candidates must be citizens of the United States or Canada.

B. All candidates must present evidence of satisfactory moral and ethical standing in the medical profession.

C. All candidates must be active members in good standing in their county and state medical societies in their state of legal residence. Under unusual and exceptional circumstances the board reserves the privilege of modifying this requirement. (This ruling shall not apply to commissioned officers of the United States regular Army or Navy or United States Public Health Service who are otherwise members of the American Medical Association.)

D. Canadian citizens applying for admission to examination must be active members of the Canadian Medical Association.

II. PROFESSIONAL QUALIFICATIONS

A. Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association at the date of graduation.

B. Satisfactory completion of an approved internship of not less than twelve months.¹

C. Approved residency or fellowship training in internal medicine according to the following plan (Plan A) or one of the alternate plans described under paragraph D.

Plan A: A residency or fellowship in internal medicine for a period of not less than three years in a hospital or other institution approved by the Council on Medical Education and Hospitals of the American Medical Association for residency or fellowship in internal medicine. In addition, two years of practice of clinical internal medicine will be required. The board will accept the following equivalents as satisfying one year only of the three years of residency or fellowship to which this paragraph refers.

1. A second year (or a part thereof) of approved internship in a hospital approved for resident training in internal medicine if limited to the medical service (or medical specialties noted under 2) for one year and if recognized as being the equivalent of an assistant residency by the Medical Director of the hospital and the Chief of the Medical Service.

2. One year of approved residency in one of the medical specialties: allergy, cardiovascular disease, gastroenterology, hematology, pulmonary diseases, neurology, pediatrics and psychiatry.

3. One year of approved residency in pathology.

4. One year as a graduate student or as an instructor in an approved medical school on a full time basis in bacteriology, biochemistry, pathology, pharmacology, physiology or internal medicine.

5. An advanced degree in the fundamental sciences.

NOTE.—Graduate training credit for the time involved will be allowed veterans and other candidates who take and satisfactorily complete postgraduate courses in internal medicine or the basic medical sciences provided by accredited medical schools. This ruling shall not apply to courses of less than three months or more than twelve months duration. A certificate of creditable performance, based in part, at least, on a formal examination upon completion of the course, will be required.

D. Alternate Training Plans: The board firmly believes that the plan of intensive training prescribed above offers the best opportunity for a young physician to prepare himself to meet his responsibilities as a specialist in internal medicine. It is recognized, however, that capable individuals may accomplish the same result in a longer period of time during which the training is less intensive. The board realizes that a number of medical graduates cannot follow the shorter and more desirable plan either because suitable residencies are not available or, in some instances, because of personal and economic reasons. Accordingly the board has modified its previous regulations governing eligibility for admission to examination. In doing so the board has not modified its standards of examination. It has liberalized its eligibility requirements for admission to

examination by accepting half time formal training and the practice of internal medicine under favorable circumstances as to professional and hospital contacts, in lieu of part of the full time requirements. It is hoped that by this means exceptional individuals may acquire a knowledge of medicine and experience in its application sufficient to qualify for certification.

The program already described (Plan A), which consists of three years of formal training in an approved residency or its equivalent, following internship, and two additional years in the practice of internal medicine, is recommended by the board. Variations in this program are now made subject to the following regulations.

1. The board will grant one year of graduate training credit, or one year in satisfaction of the requirements of practice, regardless of assignment, for active duty as a commissioned officer in the United States Army, Navy or United States Public Health Service for one year or more, beginning on or subsequent to Dec. 7, 1941 and terminating on or before Jan. 1, 1947. Commissioned officers serving less than one year prior to Jan. 1, 1947 may apply that interval as graduate training.

2. Following one year of internship and two years of approved residency,² the remaining requirements may be satisfied by: Plan B; that is, by two years of half time formal training followed by two years of practice limited to internal medicine, or by Plan C; that is, by five years of practice limited to internal medicine.

3. Following one year internship and one year of approved residency, the remaining requirements may be satisfied by:

Plan D³; that is, by four years of half time formal training followed by two years of practice limited to internal medicine; or by:

Plan E³; that is, by two years of half time formal training followed by five years of practice limited to internal medicine, or by:

Plan F; that is, by eight years of practice limited to internal medicine.

4. In every instance at least two years of practice in internal medicine must be included, but in instances in which four years of practice are substituted for one year of residency, only one additional year of practice will be required; when more than eight years of practice are substituted for two years of residency an additional year of practice will not be required.

5. Physicians who have practiced internal medicine for twelve years following an approved internship may qualify for the examinations without further training (Plan G).

Half time formal training under expanded plans B, D and E is defined as follows:

1. Half-time⁴ as an instructor in clinical medicine in a recognized medical school in the United States or Canada.

2. Half-time⁴ in a research fellowship sponsored by a recognized medical school in the United States or Canada.

3. Half time⁴ as a graduate student in an approved graduate medical school in the United States or Canada.

E. Practice Requirements: A period of not less than two years of practice in the general field of clinical internal medicine or in the more specialized branches of medicine. (See exceptions, paragraph 4. This requirement may be satisfied by independent practice or in association with a recognized internist.

NOTE: Although in general the board believes it desirable to complete the three years of formal training before satisfying the requirements of practice a reversal of this order is acceptable.

F. Graduates of Foreign Schools: At the present time neither the Council on Medical Education of the American Medical Association nor any other educational agency in the United States has the machinery to evaluate adequately the quality of foreign medical education. This board must, therefore, evaluate

1. During the period in which the 9-9-9 program was in effect an approved internship of nine months will satisfy the requirement of twelve months. A residency of nine months is considered as nine months only.

2. For the second year of approved residency one of the equivalents described under C may be substituted.

3. Refer to description of half-time formal training.

4. Certification by the head of department in which the work was done is required.

the fundamental educational credentials and other qualifications of each individual candidate educated abroad who applies for admission to examination. (Requirements for graduates of foreign schools may be obtained on request to the board—One West Main Street, Madison 3, Wis.).

G. Candidates Graduating Prior to 1937: The requirement of three years of graduate training will not apply to candidates graduating from approved medical schools in the United States and Canada in 1936 or previous thereto, provided such candidates have limited their work to the field of internal medicine for at least two years, and provided each candidate is recognized as an internist by his colleagues in his community.

H. "Preceptor Training": Preceptor type training is not recognized in satisfaction of any part of the three year requirement of formal graduate training.

I. The board will grant one year of graduate training credit, or one year in satisfaction of the requirements of practice, regardless of assignment, for active duty as a commissioned officer in the United States Army, Navy, or United States Public Health Service for one year or more, beginning on or subsequent to Dec. 7, 1941 and terminating on or before Jan. 1, 1947.

Depending upon the nature of the duty assignments, after Jan. 1, 1947 active duty as a commissioned officer in the United States Army Reserve Corps, United States Naval Reserve Corps or United States Public Health Service may be applied in satisfaction of one year of the requirements of practice but will not be regarded as satisfying any part of the graduate training requirements, unless the officer is assigned as a resident in internal medicine, neurology, psychiatry or pathology in an Army, Navy or United States Marine hospital which is approved by the Council on Medical Education and Hospitals of the American Medical Association for resident training in the divisions of medicine referred to.

One written examination will be held each year, effective Jan. 1, 1949. Examinations will be held on the third Monday in October of each year. Applications for this examination must be filed by May 1 of the year concerned.

PRINCIPLES OF TRAINING

The American Board of Internal Medicine is interested in the fact that the candidate has embarked on a career of study voluntarily and has thereby expressed the desire to excel and to participate personally in the world's progress in medicine.

Preparation must be based on years of continuous thoughtful study. Therefore, in suggesting a program for those who wish advice, the board hopes to assist the candidates to avoid inferior and superficial programs which may lead to failure and disappointment in later years.

The board believes that all internists should have a sound fundamental knowledge of anatomy, bacteriology, biochemistry, pathology, pharmacology and physiology. Such knowledge is essential to the continued progress of any internist. The board anticipates that adequate training will be obtained in the basic sciences as applied to internal medicine during a formal three year residency program.

The board wishes to emphasize that time and training are but a means to the end of acquiring a broad knowledge of internal medicine which the candidate must demonstrate to the board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge rests with the candidate. The responsibility of maintaining the standards of knowledge required for certification devolves on the board.

APPLICATION

Candidates for examination must make their application on a prescribed form which may be obtained from the office of the Assistant Secretary-Treasurer.

The application must contain a record of the candidate's premedical and medical training as well as of internships, residencies, graduate study, hospital or dispensary staff appointments, teaching positions, service in the armed forces, membership in medical societies, medical papers published and the names of three or more well known internists to whom the board may write for professional and character reference.

The application must be accompanied by one recent signed photograph of the candidate mounted on the application, and the registration and examination fee of \$40, which fee will cover both the written and oral examinations. An additional fee of \$10 will be required when the certificate is issued.

A fee of \$20 is required for each additional oral examination.

Candidates who have taken one written examination or one oral examination while on active duty overseas as a commissioned officer in the United States Army, Navy, or Public Health Service will be authorized to take a fourth written examination or a fourth oral examination if necessary. This regulation will not apply to candidates in the armed forces who took their written or oral examinations in the United States.

METHOD OF EXAMINATION

The examinations for certification by the board comprise two parts: Part I is written; Part II is clinical and is an oral examination. The written examination is held simultaneously in different sections of the United States and Canada on the third Monday of February and October of each year. This examination is divided into a morning and afternoon period, for each of which three hours are allowed. The questions asked are framed in such manner as the board elects; in general, there will be questions designed to test the applicant's knowledge of applied physiology, anatomy, physiological chemistry, pathology, bacteriology and pharmacology as related to internal medicine, and his basic clinical acumen.

Candidates must pass the written examination before admission to the oral examination will be authorized. The oral examination is conducted under the direct supervision of the board. It is held near the time and place of the annual meetings of the American Medical Association and the American College of Physicians. The examination is conducted at the bedside of the patient. Each candidate is assigned 2 or more patients and is expected to be sufficiently familiar with whatever problems present themselves to satisfy the board of his clinical expertness.

REEXAMINATION

Effective Jan. 1, 1946, not more than three written examinations will be authorized. The interval between the first and the second written examination will be one year. The interval between the second and the third written examination will be not less than two years. A longer period may be required by the board. A fee of \$10 is required for each additional written examination.

This ruling does not make it mandatory for a candidate to repeat the examination within one or two years, since each candidate may elect a longer interval.

Not more than three oral examinations are authorized. The interval between the first and the second oral examination will be one year. The interval between the second and the third oral examination will be not less than two years. A longer period may be required by the board. Candidates may elect a longer interval if desired. A fee of \$10 is required for each additional oral examination.

CERTIFICATES

The certificate issued by the American Board of Internal Medicine shall be in such form as to comply with the articles of incorporation and the by-laws and shall be signed by the officers and members of the board and shall bear the official seal of the board.

Certificates of the board will be issued to candidates who have satisfactorily completed the written and oral examinations and have been found qualified by the board to practice the specialty of internal medicine. Specialty certification will be designated on the certificate, for those so certified.

ADVISORY BOARDS

Allergy, cardiovascular disease, gastroenterology and pulmonary diseases are recognized specialties.

All candidates must pass the written and oral examinations in internal medicine before admission to examination in a specialty of medicine. The specialty examinations are oral

only and may be taken the day following the examination in general medicine or at any other regularly scheduled oral examination.

Applications for consideration in the specialties referred to must be approved by the advisory board concerned and confirmed by this board.

Application forms will be forwarded upon request to the office of the Assistant Secretary-Treasurer.

AMERICAN BOARD OF NEUROLOGICAL SURGERY

MAX M. PEET, Chairman, Ann Arbor, Mich.

WINCHELL McK. CRAIG, Vice-Chairman, Rochester, Minn.

WILLIAM J. GERMAN, Secretary-Treasurer, 789 Howard Avenue, New Haven 4, Conn.

A. W. ADSON, Rochester, Minn.

C. C. COLEMAN, Richmond, Va.

LEO M. DAVIDOFF, New York.

JOSEPH P. EVANS, Cincinnati.

HOWARD C. NAFFZIGER, San Francisco.

ERIC OLDBERG, Chicago.

BRONSON S. RAY, New York.

R. GLEN SPURLING, Louisville, Ky.

HARRY WILKINS, Oklahoma City.

Eligibility for Examination: To be eligible for examination and certification by the Board, all candidates must possess the preliminary and basic medical qualifications required by the Advisory Board for Medical Specialties as applied to all specialties as follows:

A. GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession satisfactory to the Board of Directors.
2. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.
3. Those who limit their surgical activities to the practice of neurological surgery.
4. It shall be discretionary with the board to accept for examination candidates who have been in practice more than six years but whose formal training fails to meet the full requirements.
5. Properly qualified candidates who are permanent residents in and citizens of other countries and are legally qualified to practice medicine there, and who have received their training in neurological surgery in the United States of America or Canada may apply for certification by The American Board of Neurological Surgery.

B. PROFESSIONAL STANDING

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school which is acceptable to the American Board of Neurological Surgery, Inc.
2. Completion of a surgical internship of not less than one year in a hospital approved by the same Council, or its equivalent in the opinion of the Board.

C. SPECIAL TRAINING

A period of graduate study in a recognized graduate school of medicine of not less than three years beyond the intern year, or in an approved hospital or under a sponsorship acceptable to the American Board of Neurological Surgery, Inc., for the training of neurological surgeons.

This period of special training shall be of such a character that the relation of the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry is emphasized. Knowledge of these sciences as applied to practice of neurological surgery will be required in the examination.

An additional period of not less than two years in the practice of neurological surgery.

APPLICATIONS

An application on the official application blank in such form as may be adopted from time to time by the Board of Directors, in order to be considered at any meeting, must be in the hands of the secretary-treasurer of the board not less than sixty days before the date of such meeting.

The secretary-treasurer of the board on receipt of an application shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary-treasurer may deem desirable, after which he shall forward the application to the Committee on Credentials. This committee shall consider the application and other information available and notify the secretary-treasurer its recommendation whether or not the applicant is acceptable. The certification of a candidate shall be approved by a majority of the members of the entire board at any meeting held for such certification.

PAYMENT OF FEES

The fee for certification, with or without examination, shall be seventy-five dollars (\$75).

The candidate for examination on filing his application shall accompany it with an application fee of twenty-five dollars (\$25). When notified by the secretary-treasurer that he is eligible for examination he shall send the examination fee of fifty dollars (\$50) to the Secretary-Treasurer at least two weeks before the date of the examination. The application fee will be returned if the candidate is not accepted for examination.

REEXAMINATION

A candidate who has failed in one examination is eligible to reexamination in the subject, or subjects, in which he failed, within three years, on payment of a reexamination fee of ten dollars (\$10). A candidate who has failed in one examination and who does not apply for reexamination within three years or a person who has applied within that time but who has failed a second time will be considered a new applicant.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

WALTER T. DANNREUTHER, President, New York.

JOSEPH L. BAER, Vice President, Chicago.

NORMAN F. MILLER, Vice President, Ann Arbor, Mich.

PAUL TITUS, Secretary-Treasurer, 1015 Highland Building, Pittsburgh 6.

WILLARD R. COOKE, Galveston, Texas.

F. BAYARD CARTER, Durham, North Carolina.

ROBERT L. FAULKNER, Cleveland.

ROBERT A. KIMBROUGH JR., Philadelphia.

DANIEL G. MORTON, San Francisco.

PREREQUISITES TO ELIGIBILITY

Each applicant before he may become eligible to receive a certificate.

1. Must have had conferred upon him a degree in medicine by an institution of learning approved by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

2. Must establish in a manner satisfactory to the Board of Directors that he is a physician duly licensed to practice medicine, and

- (a) That he is of high ethical and professional standing.
- (b) That he has received adequate training in both obstetrics and gynecology as a specialty. Training in one branch only is not acceptable. The term "adequate training" as used here shall be construed as meaning at least six months, full time, in the branch of either obstetrics or gynecology relegated to a minor role in a candidate's training and preference for practice.
3. Must make application for investigation of his credentials and a survey of his character.
4. Must assure the board that he is limiting his practice to obstetrics and/or gynecology and that he intends to continue to do so, except for military duties, having limited for at least

six months before making application. Effective Dec. 31, 1949, candidates will not be accepted who have not been in practice limited to the specialty for a minimum period of at least two years following completion of their specialty training.

5. Must have membership in the American Medical Association, or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

This board will not accept applicants for examination who are not full citizens of the United States or of Canada, though they be residents of either country. Foreign born applicants must have been certified by either the National Board of Medical Examiners or licensed to practice medicine in the United States or Canada by a state or provincial board of licensure. Notarized statements, not original citizenship papers, must be furnished when the application is filed attesting to the fact of full citizenship in the United States or Canada, if the applicant is foreign born. Further, there will be required a probationary period of at least three years from the date of licensure in the practice of medicine in these countries before such a candidate may be admitted to examination.

The board has ruled that physicians who accept male patients in their private or other practice, for operative or other care, cannot be regarded as specialists in obstetrics and gynecology, except by special ruling when this is related to active military duty.

This board deprecates engagement in fields of practice other than that in which candidates profess to be specialists. The board does not exclude from examination, however, obstetricians-gynecologists who practice abdominal surgery and urology in the female, as well as breast surgery, because of the correlation of these activities.

Military service or any other similar patriotic service, such as work with Selective Service boards, etc., has not been construed as nonlimitation of practice in violation of the board regulations.

REQUIREMENTS

The requirements for all candidates will be uniform as follows:

1. Completion of at least one year intern service in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association. This need not be a general rotating internship, although this latter is preferred.

The Board accepts the fifth or "intern" medical school year required at some schools in lieu of the usual fifth or intern "clinical training" year following graduation.

A second year general internship is to be considered as one of a candidate's years of practice. No credit will be given toward special training during a second year general internship.

2. A minimum of seven years of practice after the intern year, including at least three years of residency training in approved institutions, or adequate preceptorship training and including at least six months' post-training practice limited to the specialty. Effective Dec. 31, 1949, this latter requirement shall be increased to two years, at least, post-training practice limited to the specialty.

3. The period of special training should emphasize the relation of the basic sciences, anatomy, pathology, physiology, biochemistry and bacteriology, to the application of surgical principles which are fundamental in all branches of surgery. In addition, the candidate must understand and be trained in the following subjects: viz., the care of emergencies, shock, hemorrhage, blood replacement, electrolyte and fluid balance, protein and nitrogen balance, choice of anesthetics, chemotherapy, acidosis and alkalosis, narcotics and hypnotics, wound healing, etc.

4. Credit for graduate courses in the basic sciences which involve laboratory and didactic teaching rather than clinical experience or opportunities will be given for the time spent up to a maximum period of not more than six months regardless of the duration of the course.

PRECEPTORSHIPS

As a substitute for special residency training, service with a qualified obstetrician/gynecologist preceptor, preferably one who

has been certified by the board, may be acceptable. The exact time basis for this has not been specified, and each case must be reviewed and decided individually by the Credentials Committee after the application is submitted in the regular manner. The time allowance for this type of training will vary with the amount of work done with the preceptor. It is unusual for more than six months' credit to be given for one year of preceptorship training.

An acceptable preceptor is a specialist in obstetrics and gynecology of long experience, preferably certified by this board. His volume of office and hospital practice must be large enough to offer ample opportunity for the candidate's training. Preceptor training should include participation in procedures of office and hospital practice, including operative and obstetric responsibilities, with adequate time devoted to the studies of basic sciences and pathology and the study of current literature pertaining to this specialty. The preceptor should supervise closely the candidate's work and keep an informative record of the candidate's performance in order to facilitate the board's efforts in evaluating the adequacy of the candidate's training.

APPLICATION AND FEES

Application must be made on a special blank which will be furnished by the secretary's office, 1015 Highland Building, Pittsburgh 6, Pa., and must be forwarded with the other required credentials and the application fee to the secretary's office at least ninety days prior to the scheduled date of the Part I examinations.

The application fee is \$25 and is not returnable.

The examination fee is \$100 and is payable when the candidate is notified of acceptance for examination. This fee is not returnable after the candidate has been officially accepted by the Credentials Committee and notified to report for examination.

The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners and associate examiners serve as such without compensation other than actual expenses.

Applicants declared ineligible for admission to examination may request reopening of their applications within two years of the filing date without payment of an additional application fee. When a candidate requests that his application be reopened, he must supply the board with information which may justify such further consideration. A request for the reopening of an application declared ineligible by reason of insufficient training, nonlimitation of practice or similar items may not be made within two years. The request must have adequate supporting evidence to warrant reconsideration. This time may be reduced under exceptional circumstances.

After two ineligibility or postponement rulings on any candidate's application, an entirely new application must be submitted (with or without fee, according to current requirements) in order to bring data down to date. The essential feature of this should be evidence of additional training and experience.

Applicants declared eligible but who fail to exercise the examination privilege within three years of the date of filing the application are required to file a new and current application and to pay a new application fee.

An applicant entering military service during any national emergency and assigned to work in general surgery under conditions acceptable to the Credentials Committee may receive credit up to a maximum of six months acceptable toward his three required years of specialty training. He should specifically request such credit in making his application. The additional time may be applied toward the years of practice requirement.

An applicant serving under military orders in an Army or a Navy hospital in an obstetrical and/or gynecological service under supervision will be given the same credit as if he were working under a preceptor, if these departments are supervised diplomates of this board or recognized obstetricians-gynecologists. He may obtain full residency credit if such hospital is officially approved and listed for residency training in this specialty.

Additional time in military service with any type of general medical assignment may be applied toward the board's years of practice requirement. The Credentials Committee of the board will review and give consideration to each individual case.

Candidates should offer as sponsors or references two diplomates of this board with whom they are presently in contact, rather than men under whom they served as residents only. It is required that sponsors be from the candidate's community and currently acquainted with the candidate and his ability in his practice of the specialty.

Upon notice of acceptance for admission to examination, examination fee is due and also case records, which should be shipped by the candidate to the secretary's office as soon as possible and not later than the date of the Part I written examination.

The candidate should make immediate acknowledgment of his notice of acceptance, at which time he will notify the secretary's office approximately when to expect his case reports.

EXAMINATIONS

Part I examinations are scheduled annually for the first Friday in February. Grades cannot usually be mailed from the secretary's office until after April first following examination. Arrangements will be made for candidates to report in any convenient city where there may be a diplomate of this board to conduct or supervise the written examination which will be sent out from the board's office under sealed cover.

Special arrangement will be made through senior officers for conducting the written portion of the Part I examination for men in military service. Such candidates are requested to keep the secretary's office informed at all times of changes in their mailing addresses.

All applicants accepted for examination will be required to obtain a passing grade in both the written examination and a review of case reports (Part I), before becoming eligible for the oral-clinical and pathology examinations (Part II). The passing grade for the written examination and case reports is 75 per cent. A candidate whose grade in either or both falls below 75 per cent is conditioned.

Reexamination for the removal of conditions in Part I may be taken after one year but within three years after the first failure, without payment of an additional fee.

Candidates who successfully complete the Part I examination proceed automatically to the Part II examination held later in the year.

Candidates appearing for reexamination under a new application after two previous failures will not be required, if they have passed all or part of the Part I examinations on their first application, to repeat such examination items already successfully cleared.

PART I

Examination consists of:

1. A comprehensive written examination, conducted annually, including questions on both obstetrics and gynecology and related basic sciences. The written examination will be limited to a maximum period of three hours.

2. The filing, not later than the date of the written examination, of twenty-five obstetrical and gynecological case reports, in condensed form. Five cases may concern major illnesses, not necessarily operative. All must be of patients for whom the candidate was personally responsible. Grades on case reports submitted for review prior to the written examination will be announced simultaneously with those of the latter; candidates who take the written examination but fail to submit case reports on or before the date of the written examination cannot be given the grade on the latter until their case reports have been received and graded.

PART II

The oral-clinical and pathology examinations given all candidates are conducted by the entire board and the associate examiners usually near the time and place of the annual meeting of one or more of the national societies represented on this board. Advance announcements of examination dates and place will be made in medical journals throughout the country.

Examination consists of:

1. Oral examination before two to four examiners.

An endeavor is made to adapt the details of the oral examination to each candidate's experience and practice. The

examination is particularly directed to ascertain his familiarity with recent obstetrical and gynecological literature, the related basic sciences, the breadth of his clinical experience, and his general qualifications as a specialist in obstetrics and gynecology.

2. Pathology examination.

The candidate is expected to identify and to discuss several obstetrical and gynecological pathologic specimens and sections.

Examiners report orally upon each candidate to the assembled board, after which the results of their investigations are considered jointly by the entire board and associate examiners. After a general consideration of the details of the candidate's oral and pathology examinations, including a review of his capability and general adaptability, the candidate is passed or failed by the entire board.

The final action of the board is based upon the candidate's ethical and professional record, training and attainments, as well as on the results of his formal examination.

No conditions are given in Part II of the examination. When a candidate fails in Part II of the examination, he is not required to repeat Part I, but to take a reexamination in the oral-clinical and pathology portions only. One reexamination may be taken within three years of the original examination or first failure without reapplication or payment of an additional fee.

The candidate may reappear at the examination following the one failed by him. In applying for reappearance he should outline additional training or experience acquired in the interim. The board may, at its discretion, deny the candidate the privilege of reexamination.

Failure to exercise the privilege of reexamination within three years entails the filing of a new application with the usual application and examination fees.

After two failures in either Part I or Part II on the first application, the candidate may reapply and be readmitted to examinations once only. Exceptions to this ruling can be made only by action of the entire board in annual session, usually to be based upon evidence of additional training and experience sufficient to warrant such action.

AMERICAN BOARD OF OPHTHALMOLOGY

EVERETT L. GOAR, Chairman, Houston, Texas.

JOHN H. DUNNINGTON, Vice Chairman, New York.

S. JUDD BEACH, Secretary-Treasurer, 56 Ivie Road, Cape Cottage, Maine.

EDWIN B. DUNPHY, Boston.

CONRAD BERENS, New York.

WALTER B. LANCASTER, Boston.

FREDERICK C. CORDES, San Francisco.

ROBERT J. MASTERS, Indianapolis.

CECIL S. O'BRIEN, Iowa City.

M. HAYWARD POST, St. Louis.

ALGERNON B. REESE, New York.

GEORGIANA D. THEOBALD, Oak Park, Ill.

PHILLIPS THYGESON, San Jose, Calif.

DERRICK T. VAIL, Chicago.

WILLIAM L. BENEDICT, Rochester, Minn.

REQUIREMENTS

All candidates must comply with current board regulations regardless of time of filing application.

The secretary is not permitted to make decisions as to requirements. These rulings are made only by the Committee on Credentials after reviewing the candidate's formal application.

PREREQUISITES

1. High ethical and professional standing.

2. Full citizenship in the country where the candidate practices. (Limited to countries of North and South America, their possessions and territories.)

3. A degree from a medical school of high standing, satisfactory to the board and approved by the Council on Medical

Education and Hospitals of the American Medical Association. An applicant whose training has been received outside of the United States and Canada must present credentials satisfactory to the board and is required to have the certificate of the National Board of Medical Examiners if he has been in practice less than ten years.

4. Completion of an internship of not less than one year in a hospital approved by the same Council.

5. Not less than thirty-six months (a total of sixty months is required of candidates practicing both ophthalmology and otolaryngology) of combined study, training and practice of ophthalmology in approved medical schools, hospitals, clinics, dispensaries, laboratories, preceptorships and private practice.

GENERAL REQUIREMENTS FOR ALL CANDIDATES

1. Application forms must be filled out completely and accurately. Letters of endorsement, together with any other required credentials, must be sent to the secretary's office before the deadline date.

2. Fee of \$100 remitted with application.

3. A list of papers or books published.

4. Written qualifying test.

5. Practical examination.

6. Special review of ophthalmic surgery.

7. Membership in the American Medical Association, or such other societies as are recognized for the purpose by the Council on Medical Education and Hospitals of the American Medical Association.

FEES

For written test and original examination, \$100 (as mentioned above).

For reexamination in all subjects, \$75.

For reexamination in one or more subjects, \$35.

Written qualifying test must be taken within three years of date of application. Thereafter new application and fee are required.

The fees have been carefully computed on a basis of cost of examinations, and are used entirely for administrative expenses. Examiners serve without compensation other than actual expenses.

SPECIAL TRAINING

(Applicable so far as practicable after 1948)

This shall include:

1. Graduate study of the basic medical sciences which are fundamental to the intelligent practice of ophthalmology, particularly: anatomy, histology, embryology, optics, physiologic optics, visual physiology and psychology, pathology, bacteriology, pharmacology, disorders of ocular motility and binocular vision, perimetry, and in the skilful adjustment and use of instruments such as the ophthalmoscope, retinoscope, slit lamp and microscope. Mere factual knowledge is not sufficient; the candidate must have had training in the application of these subjects and in their use in clinical ophthalmology, especially in refraction.

2. Active clinical experience in approved hospitals, clinics, dispensaries and private practice. Library and laboratory facilities should be utilized for intensive study of cases.

The subject matter to be covered under 1 and 2 is outlined in the syllabus prepared by the board.

These requirements may be met in various ways:

BASIC STUDIES

Anatomy

Embryology and developmental abnormalities

Biochemistry

Pathology

Bacteriology and immunology

Optics and physiological optics

Ocular physiology

Relation of eye to general diseases

Therapeutics and pharmacology

Neuro-ophthalmology

These may be covered by:

A. *Graduate Study*.—By a curricular course in the basic sciences related to ophthalmology in an approved graduate medical school.

B. *Postgraduate Study*.—By courses in individual basic sciences related to ophthalmology as given at various approved institutions. The Home Study Course of the American Academy of Ophthalmology and Otolaryngology is recommended.

C. *Residency*.—By advanced study of these subjects during a residency and by correlation of the principles involved with clinical problems.

D. *Research, Fundamental and Clinical*.—By the detailed study, under supervision or as assistant to an experienced research worker, of some problem or topic which brings the basic sciences into direct relation with the concrete clinical problem.

CLINICAL EXPERIENCE

A. By residency in an approved hospital. The most desirable of these residencies have regular lectures covering the entire field of clinical ophthalmology and of the basic subjects as applied in clinical practice. Many of these have seminars at which residents report cases which they have carefully worked up. These are discussed by the other residents and by the staff and the method of presentation as well as the subject matter critically considered.

B. By residencies in hospitals where regular instruction by lectures and quizzes and seminars is not available. The syllabus issued by the board will guide the resident in his selection of topics to be studied.

C. By fellowships in ophthalmology.

D. By preceptorship with a well-trained and critical ophthalmologist.

E. After completing a residency it is of great advantage to secure a position in a clinic as fellow or assistant. This may require only part time work, but due credit will be given. Its value to the student depends on how much study he puts into it and on how competent his seniors are.

F. *Research under competent critical and sympathetic supervision* will give first hand insight into (1) the methods whereby old knowledge was and new knowledge is acquired and (2) the pitfalls which accompany attempts to enlarge the sphere of knowledge. Only in this way can the candidate evaluate basic facts in the intelligent critical way which is expected of the specialist in practice.

G. *The candidate who cannot secure the type of residency he desires* should not despair, for his progress depends far more on how he uses his opportunities than on the opportunities themselves.

WRITTEN QUALIFYING TEST

Before being accepted for examination, candidates are given a written test to ascertain their qualifications. The questions may cover any part of ophthalmology and are especially devoted to the basic studies as listed above. The written test will be given in several principal cities at the same time. Choice of cities is determined largely by the geographical distribution of candidates. Candidates found acceptable will be notified to appear for a subsequent practical and clinical examination in ophthalmology.

EXAMINATIONS

Examinations will be held annually at or near the time and place of the meeting of the American Medical Association; also at other times and places at the discretion of the board, depending on the number of applications from any region.

The board reserves the right to limit the number of candidates to be admitted to any one examination.

Candidates must be examined in all subjects listed in the sections titled Basic Studies and Practical and Clinical Examination. The time spent in preparation will count less than the knowledge and experience acquired as shown on examination.

PRACTICAL AND CLINICAL EXAMINATION

The subjects of the practical examination are as follows: (1) External Diseases, (2) Ophthalmoscopy, (3) Histopathology, (4) Refraction, (5) Motility, (6) Ophthalmic Surgery, (7) Perimetry.

1. *External Diseases of the Eye and Adnexa*.—Various methods of examination, diagnoses and treatment.

2. *Ophthalmoscopy*.—Patient will be examined by the candidate and the findings described or drawn. A candidate is required to bring his own ophthalmoscope.

3. *Pathology*.—The candidate will demonstrate familiarity with general clinical pathology as well as the etiology, pathology and bacteriology of diseases of the eye. He will be asked to examine microscopic slides and to recognize normal and pathologic histology of the eye.

4. *Refraction*.—A candidate will examine patients and show mastery of various methods, and of the principles of refraction and of retinoscopy. He should bring his own retinoscope.

5. *Motility*.—The candidate will demonstrate upon patients his familiarity with routine methods of examination and diagnosis.

6. *Ophthalmic Surgery*.—A candidate will demonstrate his surgical technic upon animal eyes. He must bring his own equipment for performing an extracapsular combined extraction of the lens.

7. *Perimetry*.—The candidate will be given an opportunity to examine patients by use of the arc perimeter, the tangent screen and the stereocampimeter. He may also be required to interpret charted fields.

SPECIAL REVIEW OF SURGICAL CASES

The board now requires of all candidates a list of ophthalmic operations performed within two years prior to examination. This list is to be presented with application.

The operations should be listed in groups of each type of surgery. The numbers of operations in each group must be totaled and the total number of all operations shown. This list must contain the following data:

1. Date.
2. Condition or conditions for which operation was performed.
3. Name and character of operation.
4. Identification by hospital or clinic number, or the name of a consultant or conferee who was present at the time of operation.

Circumstances which prevent any candidate from fulfilling this requirement should be fully explained, with detailed statement of candidate's surgical experience.

REEXAMINATION

Candidates may be reexamined as often as they desire on satisfactory evidence of adequate additional preparation and payment of reexamination fee. A minimum of one year must elapse between examinations when a candidate is conditioned in one or more subjects. A minimum of two years additional preparation is required of candidates who fail in all subjects. The board may, at its discretion, deny the candidate the privilege of reexamination.

AMERICAN BOARD OF ORTHOPEDIC SURGERY

- GUY A. CALDWELL, President, New Orleans.
ROBERT D. SCHROCK, Vice President, Omaha.
FRANCIS M. McKEEVER, Secretary-Treasurer, 1136 West 6th Street, Los Angeles 14.
J. SPENCER SPEED, Memphis.
ALLEN F. VOSHELL, Baltimore.
JOSEPH A. FREIBERG, Cincinnati.
RALPH K. GHORMLEY, Rochester, Minn.
LEROY C. ABBOTT, San Francisco.
FREMONT A. CHANDLER, Chicago.

QUALIFICATIONS OF CANDIDATES

There are certain general qualifications applicable to all candidates for examination Part I and Part II. In addition, candidates must have had special training in orthopedic surgery on one of the approved plans hereinafter described:

GENERAL QUALIFICATIONS

- (a) He must be a citizen of the United States or Canada.
- (b) He must be a graduate of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose

training has been received outside the United States or Canada, his credentials must be satisfactory to the Council on Medical Education and Hospitals of the American Medical Association and to the National Board of Medical Examiners; he must have engaged in the practice of orthopedic surgery in the United States or Canada for at least three years prior to submission of his application.

(c) He must have served an internship in a general hospital acceptable to this board. Beginning in 1951 and thereafter, applicants for Part I of the examinations must have had a year of resident training in surgery in addition to their internship.

(d) He must be duly authorized to practice medicine in the state or province of his residence.

(e) He must be ethical and have good professional standing.

(f) He must be a member of the American or Canadian Medical Association before he can be declared as eligible for Part II of the examinations.

SPECIAL QUALIFICATIONS

The trainee should realize that preparation for the specialty of orthopedic surgery should include a sound knowledge of anatomy, pathology, physiology, bacteriology and biochemistry, as these basic sciences apply to orthopedic surgery. In addition, he should have observation and first hand experience in the diagnosis, treatment, operative and postoperative care of recent and old fractures and other orthopedic problems of adults and children. However, when so desired, the trainee may substitute additional experience in fractures and adult orthopedics for the work in children's orthopedics as outlined in subsequent paragraphs.

Many hospital services approved for orthopedic training have all phases represented in such proportion that they can be given concurrently over a three year period and provide a well balanced program. Such a plan of training is probably the most desirable. However, it is possible for one to obtain satisfactory training by taking various phases of the work in different institutions (matched training). In order to help the trainee plan a well balanced program of matched training the board suggests that it be arranged as follows: adult orthopedics, one year or one third of the training period; fractures, six months or one sixth; basic sciences, six months or one sixth, and children's orthopedics, one year or one third (as previously indicated a second year of fractures and adult orthopedics may be substituted for the year of children's orthopedics).

The clinical phases of training may be obtained in hospitals or under preceptors where adequate facilities are not available for instruction in the basic sciences. In such cases the trainee should spend at least six months in the graduate department of a medical school which can offer adequate facilities and instruction in these subjects.

Upon completion of a year of internship and a year of resident training in surgery (the latter requirement being applicable to those who apply for Part I of the examinations in 1951 and thereafter), the trainee may take his special work in orthopedic surgery by one of three plans: (1) resident training on an orthopedic service of a hospital approved by the Council on Medical Education and Hospitals; (2) combined resident training and assistantship. (3) preceptorship.

1. *Resident Orthopedic Training*.—The applicant should serve for three years as a resident in orthopedic surgery on services approved by the Council on Medical Education and Hospitals. When taken as matched training, each of the required phases should be taken on a service approved for that particular phase and all phases must be covered. If the trainee elects to substitute additional adult orthopedics and fractures for a year of children's orthopedics, the training that is substituted must be acquired on an approved orthopedic service and the total period of resident training must be three years. The type of credit available in various institutions is indicated by the symbols "A," "C," "F" and "S" in the lists of approved residencies published by the Council on Medical Education and Hospitals.

2. *Combined Resident Training and Assistantship*.—In special instances, with the prior approval of the Committee on Resident Training, the board will recognize for not over two years of

training in orthopedic surgery periods of training in which the candidate combines work as resident on a hospital service, with part time assistantship to an orthopedic surgeon certified by the American Board of Orthopedic Surgery, provided that the major part of his time is spent by the candidate in the hospital service.

3. *Preceptorship*.—In certain instances, the board may recognize training under the preceptorship plan. Before taking training under a preceptor, the applicant must have completed an internship and a year of resident training in surgery. The preceptor must be a diplomate of the board whose clientele is large enough to give the trainee experience in all phases of orthopedic work. The trainee will be required to serve as full time assistant for five years, and during this period the preceptor should devote special periods of time each week, outside of the routine hours employed in the hospital and office practice, to assist the trainee with organized courses of study similar to those covered during resident training. If facilities and instruction in the related basic sciences are not available, the trainee should spend at least six months of this five year period as a student in a recognized graduate medical school where these subjects can be provided. Upon completion of the five years under a preceptor, the trainee should engage in practice, limited to orthopedic surgery, either alone or associated with a diplomate, for a further period of five years, before becoming eligible for Part II of the examinations.

PRACTICE REQUIREMENTS

These requirements are intended not only to test the applicant's determination to practice in an ethical manner and limit his practice to the special field of orthopedic surgery, but also his ability to increase his scientific knowledge. Prior to making application for Part II, applicants who took training as residents on approved orthopedic services should have had at least two years of experience in practice limited to the field of orthopedic surgery. Applicants who had preceptorship training, must have had five years of practice limited to the specialty. Applicants who did not take children's orthopedics, but substituted adult orthopedics and fractures instead, must have limited their practice to the same field in which they were trained.

CREDIT FOR SERVICE WITH THE ARMED FORCES

Because in some instances applicants who served with the armed forces acquired good training in orthopedic surgery, credits up to a maximum of two years may be allowed. Such credit, however, may be granted only on presentation of evidence that such service is, in the opinion of the Committee on Eligibility, equivalent to similar periods of approved resident training. Those requesting credits for training acquired while in the service should submit their completed Record of Professional Assignments with their application.

(a) A year of orthopedic experience with the armed forces, when approved by the committee, may be accepted to replace one of the three required years of orthopedic training.

(b) A second year of orthopedic service with the armed forces may be credited as a year toward the practice requirement.

(c) Credit for military service will be considered for assignments covered between January 1941 and July 1946.

EXAMINATIONS

APPLICATION FOR EXAMINATION

Applications for examinations, Part I and Part II, shall be filed with the secretary upon the prescribed forms and shall be accompanied by the prescribed fees which the board may fix from time to time. The required data shall be entered in type-written form and the application must be accompanied by an unmounted autographed recent photograph of the applicant. The names of two diplomates of the board shall be supplied by the candidate for reference.

The completed application must be filed with the secretary at least sixty days prior to date set for examination.

The data submitted in each application must be checked and verified in the offices of the American Medical Association.

Letters of reference shall be obtained by the secretary from diplomates whose names have been submitted by the applicant. Additional information may be sought from other available sources.

If an application has been approved, the candidate will be notified by the secretary and should then forward the required fee for the examination, Part I or Part II, as the case may be.

EXAMINATIONS

Applicants for certification will be required to take the examination of the Board in two parts. No applicant shall be permitted to take both parts of the examination at the same time, nor can he be permitted to take Part II until he has successfully passed Part I. These may be held in different places and on different dates to meet the needs and convenience of candidates and board members. Announcement of the time and place for examination will be made through the medical journals.

EXAMINATION, PART I

(a) *Eligibility for Examination, Part I*.—Minimum requirements for eligibility for examination, Part I, shall consist of completion of an internship (and a year of resident training in surgery effective for Part I in 1951), followed by at least a year of resident training in orthopedic surgery on an approved service.

Applicants who have completed more than this minimum requirement are eligible for Part I at any time up to completion of their full requirements; however, candidates who are fully qualified must submit application for Part I and successfully pass this examination before submitting application for Part II.

Candidates who make application based on preceptorship training will be considered by the Committee on Eligibility upon completion of an internship and a year of resident training in surgery, followed by five years as a full time assistant under a preceptor who is a diplomate of the board.

(b) *Examination, Part I*.—This part shall consist of a written examination and oral interviews covering those parts of anatomy, pathology, physiology and biochemistry related to surgery and orthopedics. In addition there will be questions on fundamental surgical principles, elementary fractures and orthopedic procedures, history taking and physical examination.

EXAMINATION, PART II

(a) *Eligibility for Examination, Part II*.—Candidates applying for examination, Part II, must have successfully passed Part I and must have completed the prescribed training and practice periods, as defined in Article 7, Section 2.

A separate application for Part II must be completed and forwarded to the secretary, together with the required application fee, at the specified time.

(b) *Examination, Part II*.—This part of the examination will be given in only one city once each year. It will consist of oral quizzes and a written examination covering the advanced work in all phases of orthopedic surgery. The oral examinations will include an interview in anatomy, pathology, fractures, congenital and acquired deformities, static and postural defects and other orthopedic subjects.

(c) Applicants who have qualified with a year of children's orthopedics will have separate written and oral questions related to this phase of orthopedic surgery.

REEXAMINATION

An applicant who fails to pass Part I or Part II of the examinations may be reexamined a second and third time in each part by paying the prescribed examination fee each time he is reexamined. Additional application fees are not required for reexamination. The applicant who fails must appear for his second or third reexamination within three years after the first failure. After three years a new application with the appropriate fee must be submitted.

After three successive failures in Part I or Part II of the examinations the applicant must have had additional graduate training in orthopedic surgery before submitting a new application.

TIMES AND PLACES FOR EXAMINATION

Examination, Part I, will be given probably during May of each year in various centers that will be designated by the board. The secretary will give applicants advance notice of the date, place and hour.

Examination, Part II, will be given in one place and probably not oftener than once each year. As a rule it will be in connection with the meeting of the American Academy of Orthopedic Surgeons and will precede the meeting.

AMERICAN BOARD OF OTOLARYNGOLOGY

OFFICERS OF THE BOARD

H. I. LILLIE, President, Rochester, Minn.
ARTHUR W. PROETZ, Vice President, St. Louis.
DEAN M. LIERLE, Secretary-Treasurer, University Hospitals, Iowa City.

SENIOR COUNSELORS

GEORGE M. COATES, Philadelphia.
RALPH F. FENTON, Portland, Ore.
PERRY G. GOLDSMITH, Toronto, Canada.
HARRIS P. MOSHER, Marblehead, Mass.
W. E. SAUER, St. Louis.

JOHN J. SHEA, Memphis, Tenn.
O. E. VAN ALYEA, Chicago.
FLETCHER D. WOODWARD, Charlottesville.

ASSISTANT

RUSSELL M. DECKER, Pasadena, Calif.

REQUIREMENTS

The following qualifications of candidates for examination are required by the Board:

1. A candidate acceptable for the examination (1) must have been a citizen of the United States (or Dominion of Canada) for at least three years; (2) must have been a graduate for four years or more (five years after 1950) of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association; (3) must have had at least one year's general internship in a hospital approved by the American Medical Association or other nationally recognized organization; (4) must be of good moral character and ethical in his professional relations. Graduates of foreign medical schools should have passed the examination of the National Medical Board. Candidates who have become natural-

ized citizens must give proof of their medical education and graduate training. Candidates from foreign countries must be permanent residents and citizens thereof, and meet the general requirements above.

2. A candidate must be a member of the American Medical Association, the Canadian Medical Association, or other medical societies of equal standing recognized by the Council on Medical Education and Hospitals of the American Medical Association.

3. Each candidate must have had acceptable training and be competent in the applied basic sciences fundamental to the intelligent practice of otolaryngology. Anatomy of the ear, nose, throat, neck, chest, esophagus and nervous systems, pathology, bacteriology, physiology didactic otolaryngology and fundamentals of surgery are required. These requirements may be fulfilled in residency training or in an organized post-graduate course.

4. EFFECTIVE UNTIL 1950—a candidate must have completed two years' residency in otolaryngology or three years' residency in ophthalmoto-otolaryngology and have restricted his practice to otolaryngology (or ophthalmoto-otolaryngology) for a minimum of three years or four years respectively, which may include the period of training.

5. EFFECTIVE UNTIL 1950—five years' practice limited to otolaryngology (or ophthalmoto-otolaryngology) may be accepted in lieu of the requirements in section 4, if the training has been under guidance or preceptorship which meets the approval of the Credentials Committee of the Board.

6. EFFECTIVE AFTER JULY 1, 1950—candidates must have completed a course of three years' study in otolaryngology, or four years' study if ophthalmology is included (in which case there must be a minimum of 50 per cent spent in the study of otolaryngology). The three years may have been spent in a residency which includes study of the basic sciences as specified in section 3, approved by the Board and the Council of Medical Education and Hospitals of the American Medical Association, or the candidate may have completed an organized course in the basic sciences and approved training in a residency which would give a total of three years' study in the specialty. A year's residency in surgery or medicine, or a two years' rotating internship, may be accepted as the equivalent of one year's training in otolaryngology. In addition to the above, the candidate must have had a minimum of one year in practice limited to the specialty.

7. EFFECTIVE AFTER JULY 1, 1950—a candidate, in addition to the requirements in sections 1, 2 and 3, may qualify for examination if he has limited his practice to otolaryngology (or ophthalmoto-otolaryngology) for six years under the supervision and direction of practitioners in the specialty approved by the board, in association with a hospital staff approved by the Council on Medical Education and Hospitals of the American Medical Association.

8. Candidates who cannot meet all the above requirements may be accepted for examination in exceptional circumstances, but only upon the recommendations of the board.

9. A limited certificate in one of the subspecialties of otolaryngology may be issued at the discretion of the board to an exceptionally well qualified individual in the special field in which the certificate is desired.

APPLICATION AND FEES

1. Application must be made in duplicate on special blanks procured from the secretary. The completed application blanks must be returned to the secretary, together with the other required credentials, at least one hundred and twenty days in advance of the examination at which the candidate desires to appear.

2. The applications must be accompanied by two small photographs of the candidate, together with verification of the period of enrolment from the institutions where training in otolaryngology was obtained, and the names of two or more otolaryngologists, preferably diplomates of the board, from the

vicinity of the candidate's place of residency, to be used as references.

3. The fee for the examination is \$100, no part of which is returnable. Of this sum \$25 must accompany the application. No application will be acted upon until the \$25 application fee is received. The balance of the fee—\$75—must be paid to the secretary upon notification that the candidate has been accepted for examination and at least ninety days in advance of the date of examination. A reexamination fee of \$50 is required of candidates conditioned in one or more subjects.

4. The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expense.

5. The application remains valid for three years. An applicant must appear for examination within this time or forfeit the fee.

6. Candidates whose credentials have been found satisfactory and who meet the requirements of the board will be notified ninety days prior to the date of examination. The number of candidates who can be admitted to any one examination is limited. Due to the large number of applications on file, delay in assignment for examination may be inevitable. Appointments will be given in the order applications are accepted.

7. The board, acting as a committee of the whole, reserves the right to reject an applicant for any reason deemed advisable and without stating the same, and the action of the board shall be final.

EXAMINATION

Examination will be held at such time and place as the judgment of the board may dictate. Advance notice of examinations will be given in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* and the several special journals devoted to otolaryngology. So far as is possible these will be held twice a year at, or near, the time and place of meeting of the American Medical Association, or special societies, and of the American Academy of Ophthalmology and Otolaryngology. The examinations cover from two to four days.

Scope.—This examination encompasses all phases of otolaryngology and peroral endoscopy, including faciomaxillary surgery, and surgery of the neck, excluding the thyroid.

The type of examination is as follows:

1. Clinical, covering the actual handling of patients, including history taking, physical and functional examinations, the use of laboratory and x-ray findings and a discussion of differential diagnosis.

2. Didactic, oral examinations covering all phases of otolaryngology.

3. Gross and microscopic pathology.

4. A written examination may be included when the board deems this advisable.

REEXAMINATION

A candidate who is conditioned in examination may be admitted to a subsequent examination after one year and within the three year period dating from his application, upon payment of an additional fee of \$50 and one hundred and twenty days' notice of intention to appear is required.

Candidates who have failed in the examination may be accepted for reexamination upon recommendations of the credentials committee. Satisfactory evidence of further study and progress will be required. A new application must be filed. The fee for reexamination for such candidates is \$100, \$25 of which must accompany the application. The balance of the fee, \$75, will be due upon notification of acceptance.

CERTIFICATION

1. A certificate granted by the board does not of itself confer or purport to confer any degree or legal qualifications, privileges or license to practice otolaryngology, nor does the board intend or attempt in any way to interfere with or limit the professional rights and activities of any duly licensed physician. Its aim is to improve the standards of practice of otolaryngology

and to certify as specialists those who voluntarily comply with its requirements and regulations.

2. The final action of the board is based upon the candidate's ethical and professional record, training and attainments, as well as on the results of his formal examinations.

AMERICAN BOARD OF PATHOLOGY

N. C. FOOT, President, New York.

F. WILLIAM SUNDERMAN, Vice President, Philadelphia.

ROBERT A. MOORE, Secretary-Treasurer, 507 Euclid Ave., St. Louis 10.

PAUL R. CANNON, Chicago.

R. PHILIP CUSTER, Philadelphia.

JOSEPH A. KASPER, Detroit.

JAMES W. KERNOHAN, Rochester, Minn.

JAMES B. McNAUGHT, Denver, Colo.

EDWIN W. SCHULTZ, Stanford University, Calif.

SHIELDS WARREN, Boston.

A. GENERAL QUALIFICATIONS

1. Satisfactory moral and ethical standing in the profession.

2. License to practice medicine or a certificate of the National Board of Medical Examiners.

3. Membership or associate membership in the American Medical Association or membership in a national society acceptable to the board by citizens of the United States (at present, American Association of Pathologists and Bacteriologists, American Society of Clinical Pathologists, American Medical Association, or American Society for Experimental Pathology). For citizens of other countries, membership in a national medical society of that country is required.

4. The applicant must devote his time primarily and principally to the practice of pathology.

B. PROFESSIONAL EDUCATION

1. Graduation from a medical school in the United States approved by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a medical school in other countries acceptable to the board.

C. SPECIAL TRAINING AND EXPERIENCE

1. The board admits candidates to examinations who are otherwise eligible and who have had either of two types of training and experience.

a. After five years, if four of the five years have been in institutions approved by the Council on Medical Education and Hospitals of the American Medical Association or by the board.

b. After eleven years if none of the training and experience has been in institutions so approved.

2. The specific requirements for those acceptable after five years are as follows:

a. Pathologic anatomy only.

(1) Four years of supervised study and training in an institution approved for residency training in pathologic anatomy by the Council on Medical Education and Hospitals of the American Medical Association or by the board. It is immaterial whether the candidate holds the title of resident or fellow or assistant. Candidates may, at their own election, substitute not to exceed twelve months of a straight or rotating clinical internship or a fellowship or instructorship in any of the pre-clinical departments of a university for one of the four years. In addition, time, not to exceed twelve months, spent in a department of pathology of an approved school of medicine after the completion of the second year of undergraduate study may be counted for full credit toward the four years.

(2) One additional year which may be a continuation of the preceding or may be independent practice of pathologic anatomy in a hospital approved by the American Medical Association or other institutions acceptable to the board.

b. Clinical pathology only.

(1) Four years of supervised study and training in an institution approved for residency training in clinical pathology by

the Council on Medical Education and Hospitals of the American Medical Association or by the board. It is immaterial whether the candidate holds the title of resident or fellow or assistant. Candidates may, at their own election, substitute not to exceed twelve months of a straight or rotating clinical internship or a fellowship or instructorship in any of the preclinical departments of a university, for one of the four years. Candidates, holding also a master's and doctorate degree in a special field of clinical pathology (bacteriology, serology, chemistry, parasitology or hematology) may obtain time credit for not more than twelve to twenty-four months toward the four years for this work regardless of whether it was taken before or after the medical degree. The evaluation of time credit will depend on how much of the broad field of clinical pathology was covered in graduate work.

(2) One additional year which may be a continuation of the preceding or may be independent practice of clinical pathology in a hospital approved by the American Medical Association or other institutions acceptable to the board.

c. Pathologic anatomy and clinical pathology.

(1) Four years of supervised study and training divided as follows:

(a) Two years of supervised study and training in pathologic anatomy as outlined in the preceding paragraph C-2-a-(1).

(b) Two years of supervised study and training in clinical pathology as outlined in the preceding paragraph C-2-b-(1). Candidates declared eligible before July 1, 1952 may at their own election substitute one year (twelve months) of a straight or rotating clinical internship for one year of this special training in clinical pathology. After July 1, 1952, all candidates applying for both pathologic anatomy and clinical pathology will be required to have two years of supervised training in clinical pathology.

(2) One additional year which may be a continuation of the preceding or may be independent practice of both pathologic anatomy and clinical pathology in a hospital approved by the American Medical Association or other institutions acceptable to the board. After July 1, 1952, candidates who elect to claim credit of one year for a clinical internship must take this fifth year as supervised study and training in clinical pathology in institutions approved for residency training in clinical pathology by the Council on Medical Education and Hospitals of the American Medical Association or by the board. Candidates declared eligible after July 1, 1952, who do not take a clinical internship, may, after four years of training as outlined in C-2-c-(1)-(a) and (b), spend the fifth year in independent practice in an institution or laboratory acceptable to the board.

Note.—As outlined in the preceding paragraphs, the total time requirements of the board are unchanged after July 1, 1952, namely, five years of study or practice after graduation from medical school (with exceptions noted in sections C-2-a-(1) and C-2-b-(1)).

3. The specific requirements for those acceptable after eleven years are as follows:

a. The practice of pathology under circumstances acceptable to the board for a period of not less than eleven years. At the election of the candidates, not to exceed one year of straight or rotating clinical internship may be substituted for one of the eleven years. For those candidates in this category who have had some special study and training in pathologic anatomy or clinical pathology acceptable under paragraphs C-2-a, b or c, double time credit will be allowed. Thus, if a person has two years of acceptable supervised study and training, only seven years of practice are required.

D. SPECIAL QUALIFICATIONS

1. Prior to Dec. 31, 1947, the board at its discretion certified candidates without examination, if the following conditions were met as of July 1, 1939:

a. That the candidate has been for a period of five years of professional rank in a department of pathology in an approved medical school; or

b. That the candidate had been practicing pathology for ten years in a senior position in a hospital having an adequate department of pathology, and approved by the Council on Medical Education and Hospitals of the American Medical Association or in an institution acceptable to the board.

CREDIT FOR MILITARY SERVICE

Credit may be allowed for training and experience in pathology in the federal services during the period July 1, 1940 to June 30, 1947. This credit for training or experience or both is given on an individual basis and will depend upon the opportunity the applicant has had as indicated by his or her medical service record in the specialty of pathology.

After July 1, 1947, credit for those military services will be given on the same basis as it is in civilian institutions, except that the rule in the preceding paragraph will not apply to reserve officers who continue on active duty or are called to active duty after that date.

SUBSPECIALTIES OF PATHOLOGY

(IN FORCE AFTER JULY 1, 1948)

Candidates who have met all general requirements and who have successfully passed the examination in pathologic anatomy and clinical pathology may apply for special designation of a subspecialty of pathologic anatomy or clinical pathology. The board, at its discretion, may approve this application and, after the candidate has successfully passed a prescribed examination, will issue a certificate reading "Pathologic Anatomy (Neuropathology)," "Clinical Pathology (Clinical Bacteriology)," etc.

Candidates who have met all general requirements and who have had five years' special training and experience in a special field of pathology which is acceptable to the board may apply to the board for certification in this special field. The board, at its discretion, may approve this application, and after the candidate has successfully passed a prescribed examination, will issue a certificate reading "Neuropathology," "Clinical Bacteriology," etc.

APPLICATION BLANK AND FEE

Application must be made on the special form which may be procured from the secretary and forwarded with other required credentials and the application fee. Applications cannot be given consideration by the board unless accompanied by the application fee.

The application or examination fee for candidates is \$35. If the candidate fails in his examination he will be admitted to a second examination after one year, but not later than three years, without additional fee. After two reexaminations, the applicant must file a new application and pay an additional fee before a fourth examination will be given.

The application fee of \$35 has been arrived at after careful consideration and is based on actual estimates of the expenses of examination and administration. None of the board members receive any compensation for their services except actual expenses incurred.

If the applicant, for any reason, is deemed ineligible for examination by the Board, his fee will be returned; however, the application fee is not returnable after the candidate has officially been accepted for examination and notified to report for the same.

EXAMINATIONS

Written and oral examinations will be held at or near the time and place of national medical meetings at the discretion of the board. If a number of applications from any region of the country are received, an examination in conjunction with a national medical meeting in that section will be arranged so that the financial outlay of the applicant in meeting the examiners will be as small as possible.

The examinations are to be based on the broad principles of pathology with emphasis on diagnosis, interpretation and technic. The applicant may apply for certification in either pathologic anatomy or clinical pathology or both.

The examinations in pathologic anatomy consist of a written test, an oral examination on gross pathology and a

practical examination in microscopic pathology. The examination in clinical pathology consists of a written test and an oral and practical examination in the six phases of clinical pathology: bacteriology, hematology, clinical chemistry, parasitology, serology and clinical microscopy.

DEFINITIONS

1. Pathologic anatomy is that branch of pathology which deals with the morphologic aspects of disease, recognition being given that that definition covers two phases of pathology.

(a) The applied phase with special attention to the description and diagnosis of gross and microscopic specimens.

(b) The academic phases of teaching and general morphologic diagnosis.

2. Clinical pathology is that branch of pathology which deals with bacteriology, immunology, clinical chemistry, parasitology, hematology, endocrinology and clinical microscopy, the application of the physical and biologic sciences to the diagnosis, prognosis and treatment of disease.

AMERICAN BOARD OF PEDIATRICS

CHARLES F. MCKHANN, President, Cleveland.

DONOVAN J. McCUNE, Vice President, New York.

LEE F. HILL, Secretary-Treasurer, 3309 Forest Ave., Des Moines, Iowa.

A. WILMOT JACOBSEN, Buffalo.

J. A. JOHNSON, Detroit.

HUGH McCULLOCH, St. Louis.

M. HINES ROBERTS, Atlanta, Ga.

EDWARD B. SHAW, San Francisco.

ASHLEY A. WEECH, Cincinnati.

JOHN MCK. MITCHELL, Executive Secretary, 6 Cushman Road, Rosemont, Pa.

APPLICANTS FOR CERTIFICATES

Requirements for Applicants.—All candidates for examination for certification must meet the following requirements:

1. Graduate from a Class A medical school.
2. One year's intern service in a recognized hospital.
3. Two years' service in an approved pediatric center.

On May 1, 1946, it was ruled that at least one year of the two years' service in the pediatric center must be in a full time pediatric internship or residency in a recognized institution. Because of the shortage of residencies, the board at this time voted that temporarily the second year of required residency training might be met in various ways.

(a) A full time academic postgraduate course of nine months in an approved pediatric center is credited for one year's work.

(b) Shorter postgraduate courses of three to four months duration must add up to a full time year.

(c) A maximum of three months' credit each is allowed for full time residency type training in allied pediatric subjects, such as pediatric allergy, pediatric psychiatry, pediatric pathology, pediatric cardiology.

(d) A maximum of six months' credit is allowed for residency training in an approved contagious disease hospital.

4. An additional term of two years of specialized study and/or practice. Credit of one year toward this requirement is allowed for military service.

5. Preceptorships are not accepted for credit toward the residency requirement, but are accepted toward the practice requirement.

The board defines service in a pediatric center as full time devoted to rounded experience in an approved hospital which includes ward and outpatient service and both therapeutic and preventive pediatrics. It is expected also, that the service will include adequate graduate training in the basic medical sciences, as well as in the clinical laboratory and public health aspects of the specialty. The time served in pediatric centers need not be continuous or spent in the same institution. The list of hospitals approved for pediatric residency training is published each year

in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (volume 137, pages 69-71 [May 1] 1948). It should be noted that some hospitals are approved for only one year of pediatric training. Careful perusal of the footnotes to the above list will indicate these hospitals. Training credit of only one year can be allowed for service in the hospitals indicated, regardless of its actual duration.

The application fee is \$125 and must be remitted with the application. Refund will be made only if the applicant is refused an examination. Applicants who failed in an examination may apply for a second examination after two years have elapsed and the candidates have presented evidence of continued study and activity in pediatrics. The fee for a second examination is \$75.

Application must be made on special blanks which may be secured from the executive secretary. These must be sent in to the executive secretary at least four months, and preferably six months, before the date on which the candidate would like to be examined. Formal applications will not be accepted until the last year of the final phase of training. Earlier filing of a preliminary information form is encouraged.

Letters from two competent pediatricians recommending each applicant must be sent to the executive secretary of the board. These letters should not accompany the application, but should be sent directly to the executive secretary. No member of the board, or official examiner, may recommend any applicant.

A list of papers or books published must be sent in with the application blanks.

EXAMINATIONS

Examinations will be held at or near the time and place of meetings of the American Academy of Pediatrics, or at other times and places at the discretion of the board, depending on the number of applicants from any region of the country. It is proposed to arrange examinations in different cities so that as little financial burden as possible will be placed on the applicants in meeting the examiners.

The purpose of these examinations is to determine the applicant's competency to practice pediatrics. This board feels that the best impression of an applicant's ability can be obtained by oral examination, although written ones may be submitted at times. However, at the present time this board is also giving a written examination at least six weeks preceding the oral examination. It is not proposed at the present time to require the applicant to send in case reports. The board feels that growth and development are fundamental parts of pediatric training.

INFORMATION ON CERTIFICATION IN ALLERGY

BY

THE AMERICAN BOARD OF PEDIATRICS

The American Board of Pediatrics, Inc., has taken final action, establishing certification in allergy as a subspecialty of pediatrics.

Certification in pediatrics by the American Board of Pediatrics is a prerequisite for such certification in allergy. Those who are already diplomates of the pediatric board and who wish to be certified in allergy must make formal application to the secretary of the American Board of Pediatrics. Those who are not yet certified in pediatrics and who desire certification in allergy as well should indicate this in their application to the board of pediatrics as examination in both subjects may be held at the same time.

The application fee for certification in allergy will be \$25 in addition to the application fee for pediatric certification.

An Advisory Committee of Allergy has been appointed to act with the Board of Pediatrics in all matters pertaining to the selection and examination of applicants for subspecialty certification. This committee is identical with the Advisory Committee on Allergy of the American Board of Internal Medicine.

The Advisory Committee on Allergy has outlined the requirements for applicants who desire examinations in the subspecialty of allergy as follows:

1. Two years, full time, in a satisfactory allergy clinic and its hospital (including training, in both allergy and pediatrics), or

2. One year, full time, in the allergy clinic and its hospital, and two additional years of full attendance on such an allergy clinic and its activities, or

3. Five years, full attendance, on such an allergy clinic and its activities, or

4. Special training under qualified preceptors, solely or in combination with aforementioned types of training, and such other training as might be felt adequate to prepare an individual for the practice of allergy.

It is further the opinion of the committee that clinics for such training should fulfil the following qualifications:

1. They should be in hospitals that have been accepted by the Council on Medical Education and Hospitals of the American Medical Association and by the American Board of Pediatrics for training and certification in pediatrics and for residencies in pediatrics or medicine.

2. The director of the Allergy Clinic shall be a diplomate certified in allergy by the American Board of Internal Medicine, or the American Board of Pediatrics.

When accepted the diplomate will receive from the American Board of Pediatrics a certificate in allergy and will be listed as a specialist in allergy.

Prospective applicants for certification in the subspecialty of allergy may apply to the secretary of the American Board of Pediatrics.

AMERICAN BOARD OF PHYSICAL MEDICINE

FRANK H. KRUSEN, Chairman, Rochester, Minn.

BENJAMIN A. STRICKLAND JR., Vice Chairman, Washington, D. C.

ROBERT L. BENNETT, Secretary-Treasurer, Georgia Warm Springs Foundation, Warm Springs, Ga.

JOHN S. COULTER, Chicago.

FRANK H. EWERHARDT, St. Louis.

KRISTIAN G. HANSSON, New York.

O. LEONARD HUDDLESTON, Los Angeles.

RICHARD KOVACS, New York.

WILLIAM H. SCHMIDT, Philadelphia.

ARTHUR L. WATKINS, Boston.

WALTER J. ZEITER, Cleveland.

QUALIFICATIONS FOR ELIGIBILITY TO CERTIFICATION

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

GENERAL QUALIFICATIONS

1. General

A. Satisfactory moral and ethical standing in the profession.

B. Membership in the American Medical Association or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. (Exceptions to the foregoing qualifications shall be made by the American Board of Physical Medicine for good and sufficient reasons.)

PROFESSIONAL QUALIFICATIONS

2. Professional

A. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.

B. Completion of an internship, preferably of the general rotating type, of not less than one year in a hospital approved by the same council.

SPECIAL TRAINING

A. A period of study after the internship of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same council and by the American Board of Physical Medicine as competent to provide a satisfactory training in physical medicine.

B. This period of specialized preparation shall include: (a) graduate training in anatomy (including kinesiology and func-

tional anatomy), physics (including radiation physics, electronics and medical instrumentation), physiology, pathology and other basic sciences which are necessary to the proper understanding of physical medicine; (b) an active experience of not less than two years in hospitals, clinics, dispensaries and diagnostic laboratories recognized by the Council and the American Board of Physical Medicine; (c) the written and oral examinations, given by the American Board of Physical Medicine, shall include questions concerning the basic sciences, clinical practice and laboratory and public health problems as related to physical medicine.

C. An additional period of not less than two years of study and/or practice in physical medicine.

METHOD OF EXAMINATION

Physical medicine includes the diagnosis and treatment of disease by means of physical agents. These physical agents include heat, water, electricity, ultraviolet and infra-red radiation and mechanical devices and agents (such as massage and therapeutic exercise).

Physical medicine has been termed medical applied biophysics. As now practiced, the special field of physical medicine includes (1) the employment of physical agents in diagnosis (as in electrical tests for reaction of degeneration or in the cold pressor test), (2) the employment of physical agents in treatment, (3) occupational therapy and (4) the physical rehabilitation of convalescent and disabled patients.

The physician who specializes in physical medicine must have a thorough knowledge of the basic sciences as related to these subjects as well as clinical practice in the various phases of physical medicine.

Written and oral examinations will be given which will assure the board that the applicant is thoroughly grounded in:

A. The basic sciences including:

(a) Anatomy (including kinesiology and functional anatomy). Because of the importance of proper knowledge of the function of muscles in conjunction with the administration of therapeutic exercise and physical reconditioning of convalescent and disabled patients, the applicant will be carefully examined concerning his knowledge in this field.

(b) Physics (including radiation physics, electronics and instrumentation). Because physical medicine deals largely with the employment of physical agents, in diagnosis and treatment, the applicant will be expected to be well informed concerning the fundamentals of medical physics. He will be expected to be familiar with such subjects as the physics of heat, ultraviolet and infra-red radiation, and electricity (including the physics of low voltage currents and high frequency currents as employed in medicine). Because of the newer developments in medical electronics and medical instrumentation, the applicant will be examined concerning these subjects.

(c) Physiology. The applicant will need to know the fundamentals of physiology, especially the physiology of movement and the physiologic effects of the various physical agents employed in medicine.

(d) Pathology. A basic knowledge of pathology as related to physical medicine will be required and questions dealing with this subject will be included in the examination.

(e) Other fundamental sciences. The applicant will be examined concerning his knowledge of such subjects as biochemistry and bacteriology as related to physical medicine.

B. The clinical aspects of physical medicine including:

(a) Thermotherapy. The various clinical applications of heat and cold both locally and generally should be thoroughly familiar to the applicant.

(b) Hydrotherapy. The methods of employing hydrotherapeutic devices and procedures will be covered in the examination.

(c) Electrotherapy. Questions concerning clinical, diagnostic and therapeutic uses of the constant current, interrupted currents, sinusoidal and high frequency currents will be included in the examination.

(d) Radiation therapy. The applicant will be examined especially concerning the diagnostic and therapeutic uses of ultraviolet and infra-red radiation. (Applicants will not be required

to answer questions concerning the therapeutic applications of roentgen rays and radium which are not included in the field of physical medicine but in the field of radiology.)

(c) Kinesitherapy. Questions concerning the clinical uses of therapeutic exercise and massage will be included in the examination.

(f) Occupational therapy. The applicant will be expected to answer questions concerning the indications for, and clinical applications of, various types of occupational therapy.

(g) Physical rehabilitation. Because of the importance of the understanding of the philosophy of convalescent reconditioning and rehabilitation of the seriously disabled person, the applicant will be expected to have a thorough knowledge of the modern developments in these phases of physical medicine.

APPLICATION

The application form shall contain a record of the candidate's premedical and medical training as well as of internships, graduate study, hospital and dispensary staff appointments, teaching positions, membership in medical societies, medical papers published, and the names of three well known physicians to whom the board may write for professional and character references.

The application shall also be accompanied by one recent, signed photograph of the candidate mounted on the application and the registration and examination fee of twenty-five dollars which fee will cover both the written and oral examinations. (In case of rejection of application, this fee will be refunded with the exception of ten dollars, which will be considered as a registration fee). An additional fee of fifty dollars will be required when the certificate is issued.

AMERICAN BOARD OF PLASTIC SURGERY

JEROME P. WEBSTER, Chairman, New York.

GORDON B. NEW, Vice Chairman, Rochester, Minn.

LOUIS T. BYARS, Secretary-Treasurer, 400 Metropolitan Bldg., St. Louis 3.

GUSTAVE AUFRICHT, New York.

BRADFORD, CANNON, Boston.

ALFRED WELLS FARMER, Toronto, Canada.

WILLIAM G. HAMM, Atlanta, Ga.

HAROLD L. D. KIRKHAM, Houston, Texas.

WILLIAM S. KISKADDEN, Los Angeles.

SUMNER L. KOCH, Chicago.

WILLIAM F. MACFEE, New York.

JAMES T. MILLÉ, Dallas, Texas.

ARTHUR NEAL OWENS, New Orleans.

GEORGE WARREN PIERCE, San Francisco.

WALLACE H. STEFFENSEN, Grand Rapids, Mich.

GENERAL ELIGIBILITY REQUIREMENTS

1. Moral and ethical standing in the profession satisfactory to the board. The board, believing that the practice of "fee splitting" is pernicious, leading as it does to a traffic in human life, will reserve the right to inquire particularly into any candidate's practice in regard to this question.

2. Membership in the American Medical Association, or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

3. Those whose activities are limited to the practice of plastic surgery.

4. This board will accept as applicants for examination only those who are full citizens of the United States or Canada. Notarized statements, not original citizenship papers, attesting to the fact of full citizenship in the United States or Canada must be furnished by foreign born applicants when the application is filed. Such candidates must have at least two years of practice in plastic surgery in North America after completing the training required by the board.

PROFESSIONAL REQUIREMENTS FOR QUALIFICATION

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school considered acceptable by this board.

2. Completion of an internship of not less than one year in a hospital approved by the same Council, or what would constitute in the opinion of the board the equivalent of such training.

3. Graduate study in general surgery for a period of not less than two years beyond the intern year, to be taken in an approved graduate school or hospital.

4. Graduate study in plastic surgery in an approved residency or preceptorship for an additional period of not less than two years, to be taken in an approved graduate school or hospital, or under auspices satisfactory to this board.

5. An additional period of not less than two years of practice in plastic surgery.

The above training may be taken in a recognized graduate school of medicine, or a resident in surgery and in plastic surgery in an acceptable hospital,¹ or under a sponsorship accredited by the American Board of Plastic Surgery for such training. By the latter statement it is meant that one may secure the necessary and specified training as an assistant to an accredited surgeon, provided suitable facilities for the education of the candidate are offered.

The period of special training should emphasize the relation of the basic sciences—*anatomy, pathology, physiology, biochemistry and bacteriology*—to the application of surgical principles which are fundamental in all branches of surgery. In addition, the candidate must understand and be trained in the following subjects: viz., the care of emergencies, shock, hemorrhage, blood replacement, electrolyte and fluid balance, protein and nitrogen balance, choice of anesthetics, chemotherapy, acidosis and alkalosis, narcotics and hypnotics, wound healing, etc.

Because of vagaries of training, such as changes from one specialty to another, interims of military duty and other service to the country, the aptitude and skill of candidates, the board may, at its discretion, review and make recommendations for or against certification of certain applicants outside of the listed qualifications and requirements.

The board reserves the privilege of requesting lists of operations done solely by the candidate for one or more years, or of requesting special and extra examinations, written, oral or practical, and of requesting any specific data concerning the candidate that may be deemed advisable before making final decision for certification.

Eligibility rulings or an evaluation of a candidate's qualifications cannot be made by the secretary or by any one member of the board. These are made only by the entire board upon recommendation of the Committee on Credentials and Requirements after a review of the candidate's formal application for such rulings.

MILITARY CREDIT

Credit for military service is given on an individual basis, each case being considered on its own merits and the amount of credit given being determined by the board when the information is submitted with the application.

CASE REPORTS

Candidates whose general eligibility and professional requirements are found satisfactory shall be required to submit twenty-five diversified case reports, together with photographs, to the secretary of the board. This group of case reports must include a variety of material from the entire body rather than a number of cases of one type, and should carry the candidate's personal deductions, conclusions and comments and should be sufficiently detailed to show if the conclusions drawn indicate a grasp of the subject and if the results justify the procedure.

1. An acceptable residency is one which has been approved by the Council on Medical Education and Hospitals of the American Medical Association jointly with this Board.

Each case report should be typewritten on paper approximately 8½ by 11 inches, separately numbered and paged, with the candidate's name on each page. Each report should be individually assembled and held by removable fasteners and should have a cover sheet with the candidate's name, the number of the case, hospital number, diagnosis and a brief summary of the case (not over 100 lines). The case reports, photographs and other data are to be filed with the permanent records of the board. Cases should be chosen from the private practice of the candidate or from the hospital or clinic service. Identification numbers of cases presented are required. The initials, color, age and occupation of each patient should be stated as should the name of the hospital where treated and dates of admission, operation and discharge. The important details of family history, if relevant, and of the previous history should be given. The history of the condition for which the candidate was consulted should be stated clearly and concisely, indicating previous treatment, if any, and the mental, social or economic factors involved. The physical examination of the patient with special reference to the existing deformities should be carefully described. All laboratory and other special examinations, such as roentgenograms, which were made, should be reported, with a statement of what was determined by them. The indications for operation and for the type of operation employed should be given: the preliminary treatment and the type of anesthesia used should be stated. A full description of the operative technic with methods of hemostasis, suture and drainage, if any, and the name of the assistant should be given. The early and late postoperative course and results should be described.

Photographs of conditions and drawings of operative technic, illustrative of each case, should be included and securely attached to each case report, with the name of the candidate and the number of the case indicated. All photographs should be made by a sharp focus lens from untouched negatives with identical lighting conditions, exposure and developing, and should show conditions before and after operations with clear detail.

If the case reports (and lists of operations when requested) are approved, the candidate will receive subsequent information regarding taking the examinations.

The board at its discretion may request certification of case reports by the hospital where the operations were performed. The following form should accompany the case reports: "I hereby certify that the planning and essential surgical procedures described herein were carried out by me as an independent operator."

A candidate must remember that these case reports are documentary evidence of his ability and that the material in them and the manner of presentation are important evidences of his ability.

EXAMINATIONS

The qualifying examinations will be divided into Part I, Written, and Part II, Oral and Practical (and written if deemed necessary).

Part I shall consist of a written examination prepared by the Examination Committee upon questions which concern the fundamental surgical principles as applied to plastic surgery. It shall be given under the supervision of a diplomate of one of the surgical specialty boards, preferably of the American Board of Plastic Surgery. The questions shall be given under the following headings: (1) theory and practice of plastic surgery; (2) applied anatomy, applied physiology; (3) pathology, bacteriology, clinical laboratory methods (pharmacology); (4) local and general anesthesia, shock and hemorrhage; (5) handling of tissues, wound healing, surgical accidents. To be considered as passing, the candidate shall be required to receive a grade of 65 per cent in each portion of the written examination and an average grade of 75 per cent on the entire written examination.

Part II: In order to be eligible for Part II of the examination, a candidate must have fulfilled the board's requirements as to preliminary training in and practice of plastic surgery, and must have successfully passed (a) the Part I, written,

examination of the Board or (b) have been certified by the American Board of Surgery with two to four extra years of accredited training in plastic surgery.

Part II shall, as far as possible, be of a practical nature, and shall be conducted in the candidate's locality by no fewer than two competent examiners selected by the board.

The clinical examination shall include any or all of the following: (1) the exhibition of patients who have undergone or who are undergoing treatment by the candidate; (2) examination, diagnosis and presentation of a plan of correction by the candidate of cases provided by the examiners; (3) oral examination of the candidate and observations made in the operating room, treatment rooms, and wards; (4) a written examination concerning plastic surgery may be given to correlate the clinical evaluation.

For those certified by the American Board of Surgery and excused from taking Part I of the examination in lieu of this certification, an oral or written examination on fundamental surgical principles as applied to plastic surgery will be given in the Part II examination.

REEXAMINATIONS

Candidates who have failed in the Part I or Part II examination may be admitted to another examination after one, two or three years have elapsed, except in such case as the board may for good and sufficient reason deny a candidate the privilege of reexamination. The candidate must give sixty days' notice requesting reexamination and pay a fee of \$25 for each reexamination in Part I and \$50 for each reexamination in Part II. The examiners conducting the first examination of a candidate will not be eligible to conduct the reexamination.

FEES

The fee for application and examination is \$100; of this sum, \$25 must accompany the application. The remaining \$75 must be paid when the candidate is notified of acceptance for examination. There will be no refunds. This fee may be increased at the discretion of the board.

The Board is a nonprofit organization. The fees of candidates are used solely for defraying the actual expenses of the board.

Because of the limited number of surgeons certified by this board it is necessary for a while to request \$10 annually from diplomates, after the first year's certification, to defray expenses of the board.

CERTIFICATION

It is the board's prerogative to determine the fitness professionally and ethically of any candidate for its certificate, and the action or decision of the American Board of Plastic Surgery regarding the certification of any candidate shall be final.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY

JOHN C. WHITEBORN, President, Baltimore.
H. HOUSTON MERRITT, Vice President, New York.
FRANCIS J. BRACELAND, Secretary-Treasurer, 102-110 Second Avenue, S. W., Rochester, Minn.
SPAFFORD ACKERLY, Louisville, Ky.
BERNARD J. ALPERS, Philadelphia.
KENNETH E. APPEL, Philadelphia.
PERCIVAL BAILEY, Chicago.
WALTER FREEMAN, Washington, D. C.
LOUIS J. KARNOSH, Cleveland.
ROLAND MACKAY, Chicago.
GEORGE H. STEVENSON, London, Ontario.
A. R. VONDERAHE, Cincinnati.

APPLICATION FOR CERTIFICATES

An application, in order to be considered at any meeting of the board, must be in the hands of the secretary of the board not less than ninety days before the date of such meeting. A

proper application form may be obtained from the secretary. Application may be made for certification in psychiatry or in neurology or in both fields. Applications will be formally considered only when made on the official application blank in such form as may be adopted from time to time by the board and when accompanied by an application fee in such amount as may be fixed by the board.

The secretary of the board on receipt of an application shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary may deem desirable and shall verify the candidate's record from the biographical records of the American Medical Association, after which he shall forward the application to the Committee on Credentials. This committee shall consider the application and other information available and notify the secretary whether the application is accepted. The certification of a candidate in either psychiatry or neurology, or both, shall be approved by a majority of the members of the entire board at a meeting held for such certification.

FORM OF CERTIFICATION

There shall be separate certification in psychiatry and in neurology and two certifications or a combined certification for those qualified in both fields. The certifications shall be in such form as is approved by the Board of Directors.

GENERAL REQUIREMENTS FOR APPLICANTS

Each applicant for a certificate must establish that—

(a) He is a physician duly licensed by law to practice medicine.

(b) He is of high ethical and professional standing.

(c) He is now a member of the American Medical Association, or a member of such medical societies as are recognized for purposes of certification by the Council on Medical Education and Hospitals of the American Medical Association. Exceptions to the foregoing may be made at the discretion of the board for good and sufficient reasons.

(d) He has received adequate training in psychiatry or neurology, or both, as a specialty.

CLASSES OF APPLICANTS

Class A.—Applicants who graduated from medical school before the foundation of the board (1934) will not be held to the strict interpretation of the published requirements in formal graduate training. Under such circumstances the board will consider the training and experience of the applicant and decide whether or not he will be admitted to the examination.

Class B.—Candidates graduated from a medical school after 1934 shall fulfil the following requirements.

PROFESSIONAL EDUCATION

1. Graduation from a medical school in the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose training has been received outside the United States and Canada, his credentials must be satisfactory to the aforementioned Council and the Advisory Board for medical specialties.

2. Completion of a year's internship approved by the same Council in general medicine, general surgery, pediatrics or a rotating internship.

3. The nine months' wartime internships, assistant residencies or residencies will be accepted as an equivalent of one year.

SPECIAL TRAINING

(These requirements will be rigidly enforced after Jan. 1, 1948).

Admission to the examination for certification in psychiatry or neurology requires a total experience of not less than five years.

There shall be a period of three years of full time study in institutions recognized by the Council on Medical Education

and Hospitals of the American Medical Association, and approved by this board as competent to provide training in psychiatry or neurology. A candidate may submit to the board evidence of special training in psychiatry or neurology not covered in these specifications for its evaluation and approval.

In addition to these three years of training under supervision, each candidate should have two years of clinical practice with major responsibility for the care of patients.

This training for psychiatrists should include clinical work with psychoneurotic and psychotic patients, combined with the study of basic psychiatric sciences, medical and social psychology, psychopathology, psychotherapy and the physiological therapies, including a basic knowledge of the form, function and pertinent pathology of the nervous system. This training should be supervised and guided by teachers competent to develop skill and understanding in the utilization of such basic knowledge in dealing with patients. Mere factual knowledge is not sufficient. This training period should include instruction in the psychiatric aspects of general medical and surgical conditions and the behavior disorders of children and adolescents sufficient to develop practical ability to direct the treatment of such conditions. It should also include collaborative work with social workers, clinical psychologists, courts and other social agencies. The training program of the candidate for certification in psychiatry should include sufficient training in neurology to recognize and to evaluate the evidences of organic neurological disease.

The training for neurologists should be based on clinical work with adults and children with neurological disorders, including the neurological complications of medical and surgical conditions. This shall be combined with study of basic neurological sciences, neuroanatomy, neurophysiology, neuropathology and neurooentogenology. This training should be supervised and guided by teachers competent to develop skill and understanding in the utilization of such basic knowledge in dealing with patients. Mere factual knowledge is not sufficient. This training should include sufficient psychiatry to enable the candidate to recognize and evaluate the common psychiatric reactions.

Candidates seeking certification in both neurology and psychiatry or supplementary certification in one after being certified in the other, must submit evidence satisfactory to the board of an additional two years of full time basic training in the supplementary specialty.

Thus, no candidate is eligible for examination by the board until he has completed at least five years of special training and experience in neurology or psychiatry for a single certificate, or at least seven years of training and experience for certification in both neurology and psychiatry.

TRAINING IN THE ARMED FORCES

Credit will be granted for one year of wartime service in the Army, Navy, Public Health Service and Veterans Administration. Further credit for basic training will be granted only if the training has been received in an institution recognized by the Council on Medical Education and Hospitals of the American Medical Association and approved by this board. Time beyond one year spent in the above Government agencies may be credited to experience, providing the candidate has been regularly assigned to a service in neurology or psychiatry.

EXAMINATIONS

Date and places of examinations are set by the board at its discretion and are announced in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, in the *American Journal of Psychiatry*, in the *Journal of Nervous and Mental Diseases*, and in the *Archives of Neurology and Psychiatry*.

The examinations are designed to test the competence of the candidates. There will be separate examinations for certification in psychiatry and in neurology. The board requires some proficiency in neurology on the part of those it certifies in psychiatry and vice versa, but examines the candidate in accordance with the certificate he seeks. The examinations will be of such type that no adequately trained individual will

fail; yet they will be sufficiently searching so that the specialist in fact may be separated from the specialist in name. The practical examination will include the examination of patients under the supervision of the examiner. The manner of examining patients, and the reasoning and deductions therefrom, will constitute an important part of the examination. Oral and practical examinations will be given in the basic sciences with special regard to their clinical implications.

PAYMENT OF FEES

The candidate upon filing his application shall accompany it with an application fee of \$25 which is not returnable. When notified by the secretary that he is eligible for examination, he shall send the secretary an examination fee of \$25 for examination in either psychiatry or neurology. There will be separate examinations in psychiatry and in neurology. Should the applicant desire examination in both at one meeting of the board, he shall send an examination fee of \$50. A candidate who has failed in one examination is eligible for reexamination within three years upon payment of a reexamination fee of \$25. A candidate who has been conditioned in one examination is eligible for reexamination within three years upon payment of a reexamination fee of \$10. A candidate who has been certified in either psychiatry or neurology, and who has been admitted to the supplementary examination for the other certificate, shall pay an additional examination fee of \$25. The candidate who has failed twice, or one who does not apply for reexamination within three years, will be considered a new applicant.

AMERICAN BOARD OF RADIOLOGY

E. L. JENKINSON, President, Chicago.
I. H. LOCKWOOD, Vice President, Kansas City, Mo.
B. R. KIRKLIN, Secretary-Treasurer, 102-110 Second Avenue, S.W., Rochester, Minn.
RAY A. CARTER, Los Angeles.
D. S. CHILDS, Syracuse, N. Y.
L. H. GARLAND, San Francisco.
ROSS GOLDEN, New York.
H. DABNEY KERR, Iowa City.
L. C. KINNEY, San Diego, Calif.
F. W. O'BRIEN, Boston.
J. W. PIERSON, Baltimore.
U. V. PORTMANN, Cleveland.
DOUGLAS QUICK, New York.
LEO G. RIGLER, Minneapolis.
B. P. WIDMANN, Philadelphia.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in radiology and has successfully fulfilled the requirements of the board.

A certificate granted by this board does not of itself confer, or purport to confer, any degree, or legal qualifications, privileges or license to practice radiology. Certificates of the board shall be issued upon one of two forms:

1. A certificate to the effect that the applicant has been found qualified to practice radiology in all its branches.
2. A certificate to the effect that the applicant has been found qualified to practice radiology in one or more of the following special fields: (a) roentgenology; (b) diagnostic roentgenology; (c) therapeutic radiology.

DEFINITIONS

For the purposes of this Board, the following definitions are adopted:

1. Radiology is that branch of medicine which deals with the diagnostic and therapeutic application of radiant energy including roentgen rays and radium.
2. Roentgenology is that branch of radiology which deals with diagnostic and therapeutic application of roentgen rays.

3. Diagnostic roentgenology is that branch of radiology which deals with the diagnostic application of roentgen rays.

4. Therapeutic radiology is that branch of radiology which deals with the therapeutic application of roentgen rays and radium.

GENERAL REQUIREMENTS

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

A. GENERAL QUALIFICATIONS

1. Satisfactory moral and ethical standing in the profession.
2. A license to practice medicine in the state or county in which he resides.
3. Membership in the American Medical Association, or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as herein provided, membership in other societies shall not be required.
4. That the applicant holds himself out to be a specialist in radiology or one of its branches as defined under "definitions," and that he devotes his time primarily and principally (at least 75 per cent) to the practice of radiology or one of its branches.
5. That he is a citizen of the United States or Canada. Candidates from other countries must be permanent residents of that country and native citizens thereof.

B. GENERAL PROFESSIONAL EDUCATION

1. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association. If the applicant is a resident of the United States or one of its possessions and is a graduate of a medical school outside the United States or Canada, he must have a certificate of the National Board of Medical Examiners.
2. Completion of an internship of not less than one year in a hospital approved by the same Council.

C. SPECIAL TRAINING

(Applicable to candidates who begin their training on or after Jan. 1, 1942, and to all candidates examined after Jan. 1, 1945.)

1. After completion of the internship there shall be a period of special training in Radiology of not less than three years in clinics, hospitals or dispensaries recognized and approved by The American Board of Radiology and the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in radiology. This period of specialized training shall include:

(a) Graduate training in pathology, radiation physics and radiobiology. A period of six months full time training in pathologic anatomy is recommended but, where this is not possible to arrange, the student during his three year training period may, by attending pathologic conferences, postmortem examinations and studying removed tissues, receive adequate training in pathology. It is recommended that radiation physics be taught by a combination of didactic lectures, practical examples and direct clinical demonstrations.

(b) An active experience (residency) of not less than twenty-four months in an institution, the radiologic department of which is recognized and approved by The American Board of Radiology and the Council on Medical Education and Hospitals of the American Medical Association as capable of providing satisfactory training.

(c) Examination in the basic sciences of radiology as well as the clinical aspects thereof. These examinations should be given by the student's instructors in order to allow those responsible for his training to certify to the board that he is adequately prepared.

In the current emergency the Board will allow one year of military service spent in a radiology department in the

United States Army, Navy or Marine Corps to be applied toward the satisfaction of one year of graduate training.

At its annual meeting in Chicago in June 1948 the board decided to grant credit for preceptor type training provided the candidate first spends two years in an approved x-ray department on a formal residency basis. Then the board will give credit for two years' preceptorship in lieu of the third year of residency training provided the preceptor is acceptable to the board. This program is now in effect.

APPLICATIONS

The board desires to appraise the candidate's educational opportunities (premedical, medical and radiologic), the ability of his instructors, his hospital and teaching positions, his original investigations, his contributions to radiologic literature, his membership in medical societies and his local and general reputation.

For this purpose, application must be made on a special blank which may be obtained from the secretary. No application will be considered unless made on the regular application blank. This application shall be forwarded with the required data, two unmounted photographs and the fee of \$50 at least two months before the date of the examination.

FEE

A fee of \$50 must accompany each application blank. This fee will not be returned, and no application will be considered until the fee is received. This fee has been carefully computed and is used entirely for administrative purposes. Members of the board and special examiners do not receive any compensation except for actual expenses connected with holding the examinations. As the number of candidates decreases, it may become necessary to raise the fee.

EXAMINATIONS

Each year the board will hold an examination in conjunction with the annual meeting of the American Medical Association, and, when sufficient applications are on file, a second examination will be held in conjunction with the annual meeting of the American Roentgen Ray Society and/or the Radiological Society of North America.

For the present, examinations consist of practical and oral examinations, although written examinations may be added later. The examinations are designed to test the candidate's fitness to practice radiology or one of its branches as a specialty. The board will endeavor to adapt this examination to the candidate's experience and years of practice. It will try especially to ascertain the breadth of his clinical experience, his knowledge of the basic sciences of radiology, and likewise his knowledge of the recent literature on radiology, and his general qualifications as a specialist in this branch of medicine.

The examination consists of tests in film interpretation and an oral examination in pathology, physiology, radiophysics and radiobiology, as well as the clinical applications of roentgen rays and radium. The applicant is also examined in "professional adaptability," in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instruction for the purpose of overcoming his deficiencies.

REEXAMINATIONS

If the candidate fails in the first examination he will be admitted to a second examination after one year has elapsed but not more than three years. He must give sixty days' notice of his intention to appear for reexamination, and pay an additional fee of \$25. If a candidate who has failed does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of \$50.

A candidate having failed twice may, after one year has elapsed, file a new application which must be accompanied by the fee of \$50.

AMERICAN BOARD OF SURGERY

FORDYCE B. ST. JOHN, Chairman, New York.
SAMUEL C. HARVEY, Vice Chairman, New Haven.
J. STEWART RODMAN, Secretary-Treasurer, 225 S. Fifteenth Street, Philadelphia 2.
WILLIAM DEW. ANDRUS, New York.
ISAAC A. BIGGER, Richmond, Va.
EDWARD D. CHURCHILL, Boston.
WARREN H. COLE, Chicago.
WARFIELD M. FIROR, Baltimore.
HOWARD K. GRAY, Rochester, Minn.
ROBERT M. MOORE, Galveston, Texas.
FREDERICK L. REICHERT, San Francisco.
CALVIN M. SMYTH JR., Philadelphia.
NATHAN WOMACK, St. Louis.

The American Board of Surgery has recorded and clarified its requirements for eligibility for examination. The requirements have been modified for those who will begin their surgical training July 1, 1950, after one year's internship. For those whose surgical training, after one year's internship, has begun or will begin prior to July 1, 1950, the requirements are unchanged. A new booklet of information will be issued by the board early in the Fall. Full information may be obtained by writing to the board's office: Dr. J. Stewart Rodman, Secretary, 225 S. 15th Street, Philadelphia 2, Pa.

AMERICAN BOARD OF UROLOGY

GILBERT J. THOMAS, President, Beverly Hills, Calif.
CLARENCE G. BANDLER, Vice-President, New York.
HARRY CULVER, Secretary-Treasurer, Route 13, Sunnyside Road, Minneapolis 13.
GEORGE GILBERT SMITH, Brookline, Mass.
GEORGE F. CAHILL, New York.
EDGAR BURNS, New Orleans.
CHARLES C. HIGGINS, Cleveland.
A. I. DODSON, Richmond, Va.
GRAYSON CARROLL, St. Louis.

APPLICATION BLANK; REQUIREMENTS FOR ALL APPLICANTS

Application for certification must be made on a special form. This will be provided by the secretary and must be returned to him accompanied by other required data and credentials, and by \$35 of the examination fee.

Requirements for Applicants (Section 2, of the By-Laws of the American Board of Urology, Inc.).—Each applicant, before he shall become eligible to take the examination for certification in urology, must:

A. Have graduated from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association and must have completed an internship of not less than one year in a hospital approved by the same council. (The former requirement is not applicable to a candidate who graduated from an institution now extinct or whose graduation occurred before the American Medical Association had prepared a list of accredited medical schools.) All graduates of foreign medical schools must obtain a license in the state in which they propose to practice medicine and the certificate of the National Board of Medical Examiners before making application for certification.

B. Establish in a manner satisfactory to this board that he is a physician duly licensed by law to practice medicine, that he is of high ethical and professional standing and that he has received adequate special training in urology.

The board is attempting to increase and to standardize the facilities for urological training in teaching institutions, so that the expression "special training in urology" may be interpreted to include:

1. A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the Council on Medical Education and Hospitals.

of the American Medical Association as competent to provide a satisfactory training in the special field of urology.

This period of specialized preparation should include: (a) graduate training in anatomy, physiology, pathology and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in the specialty of urology; (b) an active experience of not less than eighteen months in hospital clinics, dispensaries and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the diagnosis and treatment of urological conditions; (c) examinations in the medical sciences basic to the specialty of urology, as well as in the clinical, laboratory and public health aspects.

2. An additional period of not less than two years in the practice of urology in the city from which he makes application.

These special requirements conform with the suggestions made by the Council on Medical Education and Hospitals of the American Medical Association.

C. Make application to The American Board of Urology, Inc., whose duty it shall be to investigate the applicant's credentials and make a survey of his character.

D. Assure the board that he is engaged in the practice of urology and that he intends to continue to be so engaged.

E. Membership in the American Medical Association or comparable national medical association is recommended.

FEE

The examination fee is \$100 (this fee will be increased when the expense of the examinations and other activities of the board demand). Thirty-five dollars must accompany the application. If, upon investigation, an applicant is found lacking in any of the requirements stated above, he will be notified that he is ineligible for examination. Sixty-five dollars must be paid when the applicant is accepted as a candidate for certification. Neither fee shall be returnable in any event.

If a candidate fails, he will be permitted a second examination after one year or within three years, without additional fee, but he must give sixty days' notice of his intention to appear for reexamination. After an applicant has failed twice, he must file a new application and pay a second fee.

REQUIREMENTS FOR CERTIFICATION

According to the by-laws of the American Board of Urology, Inc., applications received from applicants for certification shall be examined by the Credentials Committee and reviewed by the board. When additional data are required to complete the application, these will be requested by the secretary.

The requirements for certification include: personal appearance before the board; preparation of reports of fifty major urological cases, under the candidate's own supervision, which must contain all items essential for diagnosis, therapy, prognosis, results of treatment, etc.; oral-clinical examinations, and written examinations.

In specific instances, the board may waive any part of these requirements, with the exception of the item of personal appearance.

Each candidate will receive a notice of the time and place of the examinations, and an appointment for his personal appearance before the board.

EXAMINATIONS; REPORTS OF CASE HISTORIES

The board will hold one examination per year. This may be held in association with the annual meetings of the American Urological Association or the American Medical Association, when this is practicable, or at other times and places that the board may select, or deem expedient.

The written examinations are designed to test the candidate's preparation in, and his knowledge of, the whole field of urology including the fundamental subjects: pathology, anatomy, physiology, embryology, bacteriology, physiological chemistry and endocrinology. These may be given at the time of the oral-clinical examination or may be held on certain dates simultaneously in different parts of the country at places convenient for candidates. The examination in pathology will consist of the identification of gross specimens and sections of tissue

observed through the microscope. The examination in anatomy, physiology, embryology, bacteriology, physiological chemistry and endocrinology will be a test of the candidate's working knowledge of these subjects as they are related to the practice of urology.

The oral-clinical examination will consist of discussions of common urological conditions. The subjects forming the basis of this examination are urography; diseases of the genital organs, including the prostate; diseases of the urinary bladder and diseases of the ureters and kidneys. The examination may deal directly with data found in the reports of case histories that the candidates have submitted. It will ascertain the candidate's familiarity with recent literature, the breadth of his clinical experience and his general qualifications for practice in the specialty of urology.

The professional adaptability of each candidate will be investigated in an attempt to determine his ethical conduct and his attitude toward his patients and fellow practitioners.

The reports of 50 major urological cases must be consecutive and must have been under the candidate's own supervision. They must not be abstracted. Sufficient data should appear in these so the examiner will know that a proper history was taken and that a thorough examination, including a complete physical survey, was made.

Case reports that are copied verbatim from a hospital record are not accepted. They must be identified by the name of the hospital and the case admission numbers, with the pertinent dates. The reports must be typewritten on 8½ by 11 paper and in duplicate, but need not be on any special forms.

The data should be placed under proper headings and the arrangement of these should conform to the sequence of events incidental to the patient's admission to the hospital or clinic, the examinations made and treatment prescribed.

The board requires that all of the essential points of the history and examination, as well as a complete description of the surgical procedure, shall be given. Emphasis should be placed on the following items: preoperative diagnosis, clinical and pathological diagnosis, laboratory data, including cultures of urine and chemical analysis of calculi; summary of post-operative course with special reference to morbidity, clinical findings at time of discharge from the hospital and subsequent "follow-up" reports.

A final short paragraph must be prepared for each case. This must include the candidate's interpretation of the history in terms of pathology; the basis for the diagnosis; the facts that determined the treatment prescribed, whether surgical or otherwise; the course of treatment to be pursued following discharge from the hospital or clinic; a critical discussion of the knowledge gained from the proper handling of the case, or from the errors made (if any) in the diagnosis and method of treatment.

Complete separate index lists must accompany the reports. If the reports are obtained from more than one hospital they must be consecutive and a separate index list of each group should be provided. These lists must state the operator's name at the head of each page, the name of the patient, the hospital and admission number and the dates of operation. Statements from the superintendents of the hospitals attesting that the candidate was the operator must be included. The lists will be filed in the secretary's office for verification purposes.

Each candidate must assume personal responsibility for the data in his case reports, including autopsy findings and interpretation of urograms.

A candidate must remember that these case reports are documentary evidence of his ability and that the material in them and the manner of presentation are important evidences of his competence as an urologist.

Satisfactory case reports must be submitted before a candidate will be permitted to continue with other parts of his examination. If case reports are pronounced unsatisfactory by more than one examiner, the candidate will be informed of this and requested to prepare others.

Case reports must be submitted to the secretary of the board at least ninety days before the time set for the oral-clinical examination.

SATURDAY, SEPTEMBER 4, 1948

THE FORTY-EIGHTH ANNUAL REPORT ON MEDICAL EDUCATION

This issue of THE JOURNAL contains the forty-eighth annual report of the Council on Medical Education and Hospitals. In addition to providing detailed statistics and information for the year 1947-1948 on medical education in the United States and Canada, the report comments on a number of important developments related to medical education.

One of the most troublesome problems for medical schools today is the question of enrolments. Since the end of World War II the medical schools have been confronted with numerous appeals to increase their enrolments. The current report of the Council discusses the more important factors that prevent the schools from accepting more students. The most common limiting factor is the lack of personnel and facilities for training more students in the preclinical subjects. Sixty-six of the seventy approved medical schools in the United States have stated that they cannot admit more students with their present facilities for instruction in the preclinical departments. Thirty-seven of these schools have indicated that to admit more students an expansion of their clinical facilities would also be necessary, as have the four schools that did not report a need for additional preclinical facilities. The report discusses the many problems involved in expanding a medical school. Expansion requires much more than providing additional classroom space. Additions to laboratories and hospitals and the expansion of libraries, administrative offices and other central departments would also be necessary. The satisfactory integration of new facilities with existing facilities would present a serious problem for a number of schools. The shortage of teaching personnel as a result of the failure to train sufficient teachers during the war creates a real difficulty for all medical schools considering expansion. It should be clear from the Council's report that the problem of increasing enrolments is not simple and that no school is likely to undertake to expand its facilities unless the need is unmistakably clear and sufficient financial support to meet the expense is assured.

For the second successive year the states without medical schools sent a smaller proportion of their population to medical schools than did states with such schools. If this trend continues, as it seems likely to for the next few years, states without medical schools will undoubtedly give serious thought to establishing schools of their own or to contributing to the support of an established medical school in return for the guarantee that the school will accept a certain number of qualified applicants from the state. For several states that do not have the resources or clinical facilities to maintain a satisfactory medical school, such a plan of regional support would appear to be the most satisfactory solution.

Women comprised 9.5 per cent of all medical students in the United States during 1947-1948. This is the highest proportion of women students ever recorded. However, the percentage of women in the freshman class declined from 11.1 per cent in the preceding year to 7.9 per cent.

The enrolment of veterans in the medical schools and schools of the basic medical sciences in the United States increased from 55.6 per cent in 1946-1947 to 60.9 per cent in 1947-1948. The 1947 freshman class probably represents the peak in the admission of veterans of World War II to medical schools. Veterans numbered 73.4 per cent of the students in this class. Preliminary estimates of the composition of the 1948 freshman class indicate that about 68 per cent of the students will be veterans.

FINANCIAL SUPPORT OF MEDICAL SCHOOLS

For the school year 1948-1949 the budgets of the medical schools total \$51,000,000, which is an increase of \$8,000,000 over the total for the year 1947-1948. More than \$6,000,000 of the increase can be considered as representing additional funds available to medical schools. The balance is accounted for by differences in the methods of computing the budgets for the two periods in question. Despite the increase in funds, the need for additional financial support continues to be one of the most important problems facing the medical schools. To stabilize their present programs and undertake essential new developments, the schools estimate that they will require additional operating funds totaling about \$15,000,000 annually.

Until recent years, the financial problems of medical schools have been given little publicity. It is doubtful that either the public or the medical profession have fully realized that tuition covers only a fraction of the cost of educating a medical student and that the high quality of medical education in the United States has been made possible only by the support which medical schools have received through endowments, gifts, university funds and state and municipal tax sources.

While medical schools have been forced to increase tuition fees in recent years, student fees will still provide only 25 per cent of the cost of operating the medical schools in 1948-1949. The average annual tuition fee during the coming year will be \$513. Tuition probably cannot be raised substantially beyond this figure without barring from medical school all but the sons and daughters of the well-to-do. Medical schools cannot pass on to the student the full cost of an education which averages more than \$2,200 a year.

Medical schools apparently must turn increasingly to the public for support. The question that remains is whether the public will provide this support voluntarily or whether it will have to be provided by direct federal subsidy. With the latter solution appears the possibility that the direction and control of medical education might pass from the hands of medical educators and the medical profession. A prominent educator has pointed out the danger that federal support could lead to the disappearance of initiative and enterprise on the part of the individual schools and could also reduce the schools to "a dead level of uniformity." There is a growing conviction that before federal aid for medical schools is sought an intense effort should be made to secure additional funds from voluntary sources and local units of government. The public has been generous in supporting other medical activities and additional support should be forthcoming if the public can be fully informed of the needs of medical schools.

Most physicians probably would not favor federal subsidies for the basic support of medical education except as a last resort. Since many physicians now in practice are indebted to their medical schools for a part of the cost of their medical education, medical schools should receive the full cooperation of the profession in interesting the public in this financial problem and also in contributing generously to alumni funds.

PREMEDICAL EDUCATION

The development of medical education during the last forty years has been accompanied by significant advances in premedical education. As the medical school course has become more complex and intensive, it has become essential that students entering the study of medicine possess a basic knowledge of the natural and physical sciences and an understanding of scientific method; it is equally important that they have acquired mature habits of study. Medical schools today have no place for the student who cannot apply himself effectively to his work from the outset of his career in medical school.

Thirty-five years ago, a student could enter medical school in this country on graduation from high school, and some medical schools did not then insist on the strict fulfilment of this requirement. In 1914, the Council on Medical Education and Hospitals stipulated that approved medical schools require candidates for

admission to have had one year of college work; in 1918 this requirement was increased to two years. Since 1938 the Council has recommended a minimum of three years of college training. At present seventy-five of the eighty-seven medical schools and schools of the basic medical sciences in this country and Canada require at least three years of premedical work.

In recent years the attention of medical educators has been directed more to improving the quality than increasing the duration of premedical education. Traditionally premedical students have taken a preponderance of scientific courses. The extent to which this practice prevails is shown by Vaughn's¹ analysis of the major subjects and fields of undergraduate study of the 13,407 applicants to medical colleges who took the professional aptitude test of the Association of American Medical Colleges. This group included at least two thirds of the applicants for admission to medical schools in the fall of 1947. The analysis showed that 44 per cent of the students majored in biologic sciences, 26.4 per cent in chemistry, 11.3 per cent in premedicine, 6 per cent in other science curriculums, 2.8 per cent in psychology and only 3.8 per cent in the humanities and social sciences. For 5.7 per cent of the group the field of concentration was unclassified.

These figures reveal that the advice of medical educators that students intending to study medicine acquire a broad cultural background has largely gone unheeded. It would appear that premedical students either have not heard or have not given credence to the statements of the medical schools that in passing on a candidate for admission they are more interested in the quality than quantity of the work which he has done in scientific courses. Another explanation may lie in the feeling of premedical students that they will encounter less difficulty in medical school if they have taken a large number of scientific courses in college. For the student with borderline ability there may be some basis for this belief. It is doubtful whether it holds for the average student.

If physicians are to assume successfully the positions of leadership in the community for which their professional training qualifies them and if they are to guide intelligently the future development of their own profession in a changing society, it is essential that their knowledge should not be limited to the fields of science. Once the student enters medical school, and for many years after graduation, his time and energies are almost entirely taken up with professional studies and activities. There is little likelihood that this practice will change. Therefore, if a physician is to have a knowledge of history, literature, philosophy, political science, economics and sociology, his background in these subjects must be acquired during his undergraduate years. Medical educators are convinced of the soundness and desirability of that program.

1. Vaughn, K. W.: *Performance on the 1947 Professional Aptitude Test*, New York, Graduate Record Office, 1947.

DEFERMENT OF MEDICAL AND PREMEDICAL STUDENTS

The Selective Service Act of 1948 renders liable for service in the armed forces men between 19 and 25 years of age, the age group from which the great majority of premedical and medical students are drawn. Fortunately the Act contains a provision which makes possible the deferment of medical and premedical students under rules and regulations which the President may prescribe.

There does not seem to be any question that the deferment of medical students and physicians in their first year of internship will be authorized. Selective Service officials have indicated that they recognize the importance of allowing a sufficient number of students to continue their premedical education so that the number of students and graduates will not be reduced in the years ahead. Representatives of the Selective Service System have conferred with those of the health professions on a plan for deferring preprofessional students. While the plan that will finally be adopted has not yet been announced, it seems probable that satisfactory provisions will be made for deferring an adequate number of premedical students.

The importance of such a provision cannot be overestimated. The present Selective Service Act affects students who would in the normal course of events be entering medical school as late as the fall of 1953. Its effect on the production of physicians may thus be felt as far in the future as 1957. While veterans and others not liable for military service under the Selective Service Act now comprise a high proportion of the students in medical schools, during the next several years the schools will have to draw more and more of their students from the group liable for military service.

During the latter years of World War II no provision was made for deferring premedical students. When the Army curtailed its training program in medical schools in 1944, the schools were unable to fill all the available places in the entering class for 1945. A decrease in enrolments occurred that was kept from progressing to serious proportions the next year only by the unexpectedly early termination of the war. In the interest of the nation's health and safety, the possibility of such an eventuality cannot be allowed to occur again.

Of great importance to medical education also is the assurance of a continuing supply of trained teachers and investigators in the basic medical sciences. One of the major obstacles at present to expanding the facilities for medical education in this country is the lack of trained teachers which resulted from the almost complete cessation of graduate study during the war. At least another five years will be required to make up the deficiency of teachers. It is important, therefore, that the Selective Service System also make provisions for the deferment of an adequate number of graduate students in the basic medical sciences.

Current Comment

THE CONTINUING EDUCATION OF PHYSICIANS

In the report of the Council on Medical Education and Hospitals in this issue of *THE JOURNAL*, the total recorded attendance at refresher and continuation courses in the United States during the twelve month period July 1, 1947 to June 30, 1948 was reported to be 82,803. This figure, which does not include the attendance at 114 courses for which no attendance records were submitted, represents more than 40 per cent of the total number of living physicians in the United States. Figures for the total attendance at scientific meetings of the American Medical Association, state medical societies, county medical societies and the many special medical societies, if compiled, would furnish additional impressive evidence of the extent to which the physicians of this country voluntarily continue their education after graduation from medical school. Even these figures would not give the entire record, since they would not measure the continuing education that physicians obtain from the study of medical journals and books. Postgraduate and continuation courses were popular even before the war. After a temporary decline during the war years, the number of courses offered and the attendance have been increasing each year. It seems certain that this form of continuing education will remain one of the important methods by which physicians will fulfil their obligations to their patients of keeping abreast of advances in medical science.

RHEUMATIC BRAIN DISEASE

The incidence of rheumatic cardiac disease in a group of 500 unselected necropsies done at the Central Hospital at Indianapolis was 5 per cent. This figure, according to Breutsch,¹ probably represents the prevalence of subclinical rheumatic fever in the population of an average mental hospital located in the same geographic latitudes. Neuropathologic studies reported by the same author revealed the occurrence of rheumatic obliterating arteritis in the brain of persons with rheumatic cardiac disease. This late cerebral sequel of rheumatic fever involved mainly the small meningeal and cortical vessels, producing gross or microscopic softening in the cortex. Breutsch² stressed that rheumatic brain disease may occur months and years after the acute stage of rheumatic fever, at a time when the person is enjoying apparent good health. The late vascular lesions of rheumatic fever are not infrequently seen in middle life, and may be responsible in a number of aged patients for psychoses characteristic of that period. The finding at necropsy that 9 per cent of the patients with dementia precox showed signs of rheumatic infection involving the brain, as well as the cardiac valves, raises the question as to the possible pathogenic role of the rheumatic infection in the causation of dementia precox in a definite subgroup of cases.

ORGANIZATION SECTION

Official Notes

A.M.A. OFFICIALS VISIT JAPAN

On August 14 Dr. R. L. Sensenich, President, and Dr. E. L. Henderson, Chairman of the Board of Trustees of the American Medical Association, returned to the United States from Japan. They were members of a delegation of five who went to Japan on the invitation of General Douglas MacArthur and Brigadier General Crawford F. Sams. Drs. Ernest E. Irons, E. J. McCormick and John H. Fitzgibbon will return in a week or ten days.

Any official report made by this group will go to General MacArthur. However, Drs. Henderson and Sensenich both were enthusiastic over the reception they received in Japan, both from the American officials and the members of the Japanese medical profession. There was ample opportunity for an exchange of ideas between the American Medical Association officials and the individuals who are guiding the affairs of the Japanese profession. Under the old régime, the Japanese Medical Association was a government-controlled organization. At the present time it is organized along lines similar to those of the American Medical Association. Japanese physicians are enthusiastic over this arrangement and had many things to discuss with the Americans.

American Medical Association officers with officials from Civil Affairs Section of General MacArthur's headquarters and a group of officers and members of Japanese Medical Associations. Seated, from left to right: J. Kurosawa (reception committee), R. Inada (ex-president), Colonel Johnson, S. Kawakita (vice president), Dr. Edward J. McCormick, Dr. John H. Fitzgibbon, Dr. R. L. Sensenich, A. Takahashi (president), Dr. Elmer L. Henderson, Dr. Ernest E. Irons, T. Izeki (vice president), Major Molton, Mr. Anton, T. Kitajima (ex-president) and T. Nakayama (preceding president). Standing: Y. Minamizaki (secretary), H. Mita (supervisor), R. Kobayashi (supervisor), K. Kodama (supervisor), T. Murayama (reception committee), T. Ogata (reception committee), Y. Ono (reception committee), H. Oka (director), T. Sassa (director), H. Takeuchi (director), H. Hashimoto (reception committee), R. Azuma (director), S. Furuhashi (director), name unknown, K. Sadakata (reception committee), name unknown, K. Kato (reception committee), name unknown, name unknown, A. Saita (government official of the Welfare Ministry), and name unknown.

Washington Letter

(From a Special Correspondent)

Aug. 30, 1948.

First Meeting of Heart Council

September 8 has been scheduled for the first meeting of the new National Advisory Heart Council, which will guide the Surgeon General of U. S. Public Health Service in administering the National Heart Act enacted recently by Congress. Composed of six professional experts and six leaders in public welfare and business, the Council's membership is as follows: Drs. T. Duckett Jones, Helen Hay Whitney Foundation; Irvin Page, Cleveland Clinic; Paul D. White, Massachusetts General Hospital (Boston); Tinsley Harrison, Southwestern Medical College; B. O. Raulston, University of Southern California School of Medicine, and C. A. Elvehjem, University of Wisconsin

sin biochemist; James S. Adams, New York businessman; E. B. MacNaughton, Portland, Ore., publisher; Mrs. Albert D. Lasker, New York health worker and philanthropist; Ernst Mahler, Wisconsin businessman; Maurice Goldblatt, Chicago merchant-philanthropist, and Albert J. Wolfe, president of Touro Infirmary, New Orleans.

Construction Bids for Clinical Research Center Opened

Low bid of \$3,273,000 was submitted for the first stage of construction of the clinical research center to be erected by the U. S. Public Health Service in Bethesda, Md. Bids were opened August 10 by the Public Buildings Administration, and award of the contract was expected to follow soon thereafter. A total of \$40,000,000 has been earmarked for construction and equipment of the huge center, which will have a 500 bed hospital and house laboratories of the National Institutes of Health.

GOVERNMENT SERVICES

ARMY

REGISTRY OF CARDIOVASCULAR PATHOLOGY

The Surgeon General of the Army and the director of the Army Institute of Pathology have approved the application of the American Heart Association to sponsor a Registry of Cardiovascular Pathology with the American Registry of Pathology Division of the Institute. Dr. Wallace Yater, Washington, D. C., has been appointed chairman of the registry committee by the American Heart Association.

COURSES IN CIVILIAN INSTITUTIONS

The following additional fifteen medical department officers will attend courses in the civilian institution indicated: Col. Charles T. Young, Harvard, internal medicine; Major Robert B. Lindberg, University of Michigan, bacteriology; Major Woodrow C. Herbert, University of California, San Francisco, pharmacy; Major Frank B. Rogers, Columbia University, library science; Major George H. Zacherle, Colorado State College of Agriculture and Mechanical Arts, special problems in surgery and research in surgery; First Lieut. Robert B. Fisher, George Washington University, orthoptics; First Lieut. Robert H. Moser, Gallinger Municipal Hospital, Washington, D. C., intern training; First Lieut. William F. Colliton, Providence Hospital, Washington, intern training; First Lieut. Park C. Jeans Jr., University Hospital, Augusta, Ga., intern training; First Lieut. Armand E. Hendee, Grady Memorial Hospital, Atlanta, Ga., intern training; First Lieut. Harry W. Orme, University of Minnesota Hospital, intern training; First Lieut. Richard K. Cole, Baltimore City Hospitals, intern training; First Lieut. William H. Hall, New York Hospital, intern training, and First Lieut. Lawrence J. Get, Metropolitan Hospital, New York, intern training.

SURGEON GENERAL PRAISES WORK IN EUROPEAN THEATER

The following letter, slightly abbreviated, was written by the Surgeon General of the Army to the Chief Surgeon in the European Theater.

Dear General Noyes:

In four weeks in Germany and Austria I have seen a cross section of the Army medical activities in Europe. During some of this time one of the groups of the leading American medical consultants who visit the European Theater each month for the Surgeon General have been with me.

I have been greatly impressed with the quality of the entire Medical Department service. Both medical administrative and purely professional work is superior. Health conditions are excellent and the sick rate is extremely low.

The patients are receiving care which parallels the care and treatment patients receive in the best hospitals in the United States. Most of this care is under the immediate attention of the younger group of medical officers. These officers are able, alert, careful and show a remarkable degree of understanding. The excellent training they have received in their years of college, medical school and hospital work is clearly evident. They reflect great credit on American medicine.

It has been a privilege to see all of this at first hand. This service performed with ability and good will reflects credit on the Army. I congratulate the Medical Department personnel on their devotion to duty and to its excellent performance.

R. W. BLISS,
Major General,
The Surgeon General.

PERSONAL

Morton M. Rayman, Ph.D., has been appointed chief of the Microbiologic Branch of the Food Research Division, Quartermaster Food and Container Institute for the Armed Forces, Chicago. Dr. Rayman will direct research on the nature and factors affecting the microbiologic and histologic changes which occur during the processing and storage of foods for the armed forces.

NAVY

EXAMINATIONS FOR APPOINTMENT IN REGULAR CORPS

Examinations for the selection of candidates for appointment to the grade of lieutenant (jg) in the Medical Corps of the Navy will be held at Naval hospitals in the United States October 4-8. Graduates of approved medical schools in the United States or Canada who have completed intern training in accredited hospitals or who will complete such training within four months of the date of the examination, and who are physically and otherwise qualified, are eligible to take the examination. They must be less than 32 years of age and will be required to appear before boards of medical examiners at the Naval hospital nearest their place of residence. Following approval by the President of the United States, selected candidates will receive appointment and orders assigning them to duty in a Naval medical facility for active Naval service.

Public Law 365—80th Congress, approved Aug. 5, 1947, provides additional compensation of \$100 a month for each month of active service performed by Medical Corps officers. This is in addition to any pay or allowances that Medical Corps officers are otherwise entitled to receive. The amount paid to any one officer under this authority is limited to a total of \$36,000 computed on the basis of \$1,200 yearly over a period of thirty years' active service. Detailed information may be obtained from Naval Officer Procurement offices or from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

ADMIRAL PUGH RETURNS FROM AFRICA

Rear Admiral Lamont Pugh has returned from a visit to the Navy's medical facilities in the Mediterranean and African areas. He states that the Egyptian government and the Navy's Research Unit in Cairo have the most cordial relations and that the lease

on the property being used by the Navy in Cairo has been renewed. Admiral Pugh also visited Nairobi in Central Africa, where the Navy's Medical Research Unit which is accompanying the University of California's African expedition is located. It was in this area that the Navy captured the rare elephant shrews recently reported in THE JOURNAL. After visiting the Navy's medical facilities in Athens, Greece, as well as those of the Sixth Task Fleet and the United States Naval Forces, East Atlantic and Mediterranean, Admiral Pugh returned home via Germany and England.

JOINT SERVICES EXHIBIT

At the fiftieth annual convention of the American Hospital Association in Atlantic City, N. J., September 20, the Bureau of Medicine and Surgery will enter into a joint exhibit with its sister services showing how medical care is provided by the government services. This exhibit will point out what federal agencies operate hospital services, geographic location of these facilities, and for what persons they are operated; it will also show the number of medical personnel involved, and the training programs sponsored by each agency. The U. S. Naval Hospital Ship *Consolation* will be anchored off Atlantic City during the convention, and transportation for members of the convention to the hospital ship will operate from Starn's Pier.

RETIRED OFFICERS VOLUNTEER

The following medical officers on the retired list have volunteered for recall to active duty to aid in relieving the present shortage of medical officers: Capt. Enoch G. Brian, Coronado, Calif.; Capt. Harrison L. Wyatt, Berkeley, Calif.; Comdr. Norman J. Haverly, Long Beach, Calif., and Lieut. Bernard L. Rhodes Jr., Live Oak, Fla.

VETERANS ADMINISTRATION

RESIDENTS WANTED FOR TRAINING IN PSYCHIATRY

The Veterans Administration has immediate openings for at least one hundred young doctors interested in residency training in psychiatry or neurology. Veterans Administration hospitals offering these residencies are situated in almost every section of the country and all are under supervision of the deans' committees, mostly composed of members of university faculties of class "A" medical schools.

Applicants for residency training must be citizens of the United States, graduates of a school of medicine approved by Veterans Administration and the Council on Medical Education and Hospitals of the American Medical Association, and must have completed an internship acceptable to Veterans Administration. In general, these residencies cover a three year program of specialty training, although one and two year programs are available at most of the hospitals. Information may be obtained by writing the Chief Medical Director, Veterans Administration, Washington 25, D. C.

Residency selection and residency grades for the individual are recommended by the deans' committee supervising the program at the Veterans Administration hospital in which the applicant desires to train.

The Veterans Administration is organizing a new class of residents in psychiatry for training, for example, in the new Veterans Administration hospital in Tomah, Wis. Completion of the class is anticipated by September 1. Residents in the Tomah hospital will rotate between the university's psychiatric institute in Madison, Wis., and the hospital on a six months' basis. The residents will devote part of their school time to

the Madison Veterans Administration outpatient clinic for neuro-psychiatric patients. The new and well equipped hospital in Tomah accommodates 1,200 patients.

Three grades of residents have been established: senior at \$3,000 a year, intermediate at \$2,700 and junior at \$2,400. Grade of appointment is determined by recommendations of the deans' committee. Applicants should send a complete biographic sketch and detailed information covering medical experience to Dr. Lorenz, University of Wisconsin Medical School, 1300 University Avenue, Madison.

CHIEF OF RESEARCH APPOINTED

The Veterans Administration announces that Dr. Alfred H. Lawton, formerly dean, University of North Dakota School of Medicine at Grand Forks, has been appointed chief of general medical research in the Veterans Administration Department of Medicine and Surgery, Washington, D. C. Dr. Lawton, who assumed his new duties August 1, is supervising studies of epilepsy, hepatitis, psychoneuroses and other diseases suffered by veterans. He succeeds Dr. L. G. Welt, who resigned to return to the department of internal medicine at Yale University Medical School, New Haven, Conn. Dr. Lawton received his M.D. and Ph.D. degrees from Northwestern University, interned in Passavant Memorial Hospital, Chicago, and took residency training in surgery at the Henry Ford Hospital, Detroit. He was a research fellow at Northwestern University and later an assistant professor in the University of Arkansas School of Medicine. During World War II he served with the United States Public Health Service.

PUBLIC HEALTH SERVICE

THE NEW CLINICAL RESEARCH INSTITUTION

The Federal Security Administrator announced on June 29 plans for the clinical research institution to be constructed for the National Institutes of Health at Bethesda, Md. The thirteen story building will house the National Heart Institute, the National Institute of Mental Health, the hospital facilities of the National Cancer Institute, the National Institute of Dental Research, and services for studying patients with infectious and tropical diseases. The laboratories will occupy two thirds of the building, and the five hundred bed hospital will receive patients from all parts of the country referred by

the National Institute of Health, and partially on adjoining ground. The site is readily accessible from Washington by automobile and bus. The hospital will have the most modern facilities for patients. Throughout the institution special opportunities for study will be made available for qualified physicians and research workers. The unusual design of the building, the special equipment and research teams will give also unique postgraduate opportunities to physicians and scientists as well as members of the regular staff.

TRAINING MENTAL HEALTH PERSONNEL

The mental health program authorized by Congress in 1946 received an appropriation of \$9,028,000 for the fiscal year 1949 which will be used to finance a program of research on mental illness, to develop local mental health facilities, to train mental health personnel, all in addition to mental health activities within the U. S. Public Health Service. For grants-in-aid to states, Congress appropriated \$3,555,000, which will be allocated to states on the basis of their population, financial need and extent of the mental health problem. The National Advisory Mental Health Council recommended numerous grants to universities, hospitals and clinics to support their training programs, and these grants were approved by the Surgeon General of the Public Health Service, the Federal Security Administrator announced on July 28. The Council making these recommendations considered applications for 205 training grants and 1,099 training stipends, of which it recommended approval of 143 training grants and 561 stipends. With the funds appropriated by Congress for 1949 it was possible to award 86 training grants and 264 training stipends.

PERSONAL

Dr. Maynard H. Mires Jr. has been assigned as epidemiologist with the Mississippi State Board of Health, succeeding Dr. George Reed, who has been transferred to a Marine hospital in Ohio.

The National Institute of Health, near which the new clinical research institute will be constructed.

physicians, hospitals and other health agencies on the basis of problems under study at various times. This unusual combination of hospital and laboratory facilities within a single structure will make possible an attack by physicians and laboratory workers on clinical medical problems—cancer, heart disease, mental illness and other degenerative diseases. This institution will be located a few miles north of the District of Columbia in Maryland, partially on the estate given to the government by Mr. and Mrs. Luke I. Wilson, now used for

GENERAL

Red Cross Recruits Nurses for Poliomyelitis.—By August 1, the American Red Cross had recruited 630 nurses from chapters across the country in response to nursing needs for poliomyelitis. It had provided 306 nurses for North Carolina, a few for South Carolina, and sent 90 nurses from Midwestern states into Texas, California and scattered sections of Iowa, Illinois, the Dakotas, Minnesota, Wisconsin and Arkansas. Pacific area chapters provided 181 nurses for California and for Boise, Idaho. The National Foundation for Infantile Paralysis pays transportation and salaries for poliomyelitis nurses.

Assets of American Hospitals.—According to the 1948 Hospital Directory published by the American Hospital Association, the average cost of caring for a patient for one day in a general hospital rose from \$9.39 to \$11.09 in the year 1946-1947. The average income from patients was \$9.71, leaving a daily deficit of \$1.38 per patient to be made up through voluntary contributions and gifts from the public. General hospitals had about 151 employees for every 100 patients to maintain prevailing high standards of patient care. Hospitals spent about \$400,000,000 more in 1947 than in 1946, because of high wages, higher prices and expanded services. Hospitals in 1947 had total assets of about \$6,000,000,000, which is more than \$42 for every man, woman and child in the United States. Of that amount, general hospitals' plant valuation represents almost \$3,500,000,000, an average of \$7,500 per bed.

Society Elections.—At the joint meetings of tuberculosis associations in New York, Dr. Herbert L. Mantz, Kansas City, Mo., was chosen president, and Dr. Rollin D. Thompson, Orlando, Fla., president elect of the National Tuberculosis Association. The newly elected president of the American Trudeau Society is Dr. H. Corwin Hinshaw, Rochester, Minn., and the president elect is Dr. Kirby S. Howlett Jr., Shelton, Conn. Officers elected by the Conference of State and Provincial Health Authorities of North America at the annual meeting in Chicago, June 25-26, include Drs. John T. Phair, Toronto, Canada, president, and Russell O. Saxvik, Bismarck, North Dakota State Health Officer, secretary-treasurer. At the annual meeting of the American College of Chest Physicians in Chicago in June, Dr. Richard H. Overholt, Brookline, Mass., became president, Dr. Joseph C. Placak, Cleveland, was chosen president elect and Dr. Minas Joannides, Chicago, treasurer. Murray Kornfeld, Chicago, remains executive secretary.

Scholars in Medical Science.—Medical schools in the United States and Canada are invited by the John and Mary R. Markle Foundation to make nominations for the second group of Scholars in Medical Science on or before December 1. Each school, through the dean, may nominate one candidate. The program is designed to aid promising young men and women planning careers in academic medicine, who have not yet made their reputations. They should have completed the usual fellowship training in some area of science related to medicine and should hold, or expect to hold, in the academic year 1949-1950 a full time faculty appointment on the staff of a medical school. Grants of \$25,000, payable at the rate of \$5,000 annually, will be made to the schools over a five year period for the support of each scholar finally selected, his research, or both. Sixteen were chosen in 1948. A booklet describing the plan is available on request from the foundation, 14 Wall Street, New York 5.

Scholarships for Study of Cerebral Palsy.—Eight physicians, surgeons and therapists have been awarded scholarships for specialized training in cerebral palsy by the National Society for Crippled Children and Adults. This is the first national scholarship program established to meet the challenge of a crippling condition that disables some half million Americans, the society stated. The scholarships were made possible under the first of six \$5,000 yearly grants from Alpha Chi Omega, national women's sorority. The first eight recipients are: Arline F. Bovee, Mukileto, Wash., physical therapist at the Everett, Wash., Cerebral Palsy School; Miriam Bunce, Denver, physical therapist, Colorado Society for Crippled Children and Adults, Inc.; Dr. Harriet E. Gillette, Warm Springs, Ga., Fellow in Physical Medicine at Emory University, Atlanta, Ga.; Dr. Stanford F. Hartman, Phoenix, Ariz.; Bette Redwine, Albuquerque, N. M., physical therapist, Veterans Administration; Dr. Louis Spekter, Hartford, Conn., State Department of Health; Joan A. Schauble, Seattle, Wash., physical therapist and speech correctionist, and Harold Westlake, Ph.D., Wilmette, Ill.

World Health Organization.—As of June 15, a total of forty-three countries, including the United States, had formally joined the World Health Organization and several other nations were taking final steps toward ratification. President Truman, in signing the bill for United States membership, said, "The World Health Organization can help contribute substantially

to the attainment of the healthy, vigorous citizenry which the world needs so badly today and tomorrow."

The first World Health Assembly convened June 24 at Geneva, Switzerland, with representatives of nearly all nations of the world in attendance. The delegates had before them for consideration the report of the Interim Commission work since 1946 with proposals for concentration on four main programs—malaria, tuberculosis, maternal and child health, and venereal diseases, in addition to suggested activity for 1949 in forty-four other medical, medicosocial, and related fields.

The Expert Committee on Malaria of the World Health Organization which met in Washington last May outlined methods to implement the program on malaria, which disease, the Interim Commission states, attacks 300,000,000 persons each year, of whom about 3,000,000 die. A maternal and child health section has been established to provide machinery for the international exchange of information on all phases of this subject. The Interim Commission states also that about 50,000,000 persons suffer each year from tuberculosis, of whom about 5,000,000 die. Cases of tuberculosis are increasing rapidly, it is said, in many parts of the world. The Interim Commission plans to place special emphasis on syphilis, giving governments assistance in national and local control. According to Dr. Brock Chisholm, Executive Secretary of the Interim Commission, the delegates to the first World Health Assembly had five weeks of hard work before them.

FOREIGN

Japan

Japanese Medical Journals.—Dr. Roscoe L. Sensenich, President of the American Medical Association, on his return from a recent official visit to Japan brought a copy of volume 1, no. 1 of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION printed in the Japanese language, which contains translations of selected articles from THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION published in the United States. Authority to publish this Japanese journal was granted by the trustees of the American Medical Association. Dr. Sensenich brought back also volume I, no. 1 of *The Japanese Medical Journal*, published in Tokyo bimonthly in English as the official organ of the National Institute of Health in Japan.

Health Reform in Japan.—The Japanese Diet passed early in July two additional modern health reforms, the Venereal Disease Prevention Law and the Preventive Vaccination Law. The Venereal Disease Prevention Law provides that all pregnant women are to have a health examination to determine the presence or absence of venereal disease and all persons entering into marriage are to obtain certificates showing that they are free from venereal disease. Compulsory examination may now be performed on persons in whom there is reasonable evidence to suspect venereal disease, but if they claim there is not reasonable evidence they may appeal to a court for withdrawal of the order for a venereal disease examination. The new law requires further that doctors give instruction to patients with venereal disease as to how to protect others from their diseases and also as to the treatment which they are to follow. Doctors must report to health authorities the names and addresses of contacts and of those patients who fail to follow instructions pertaining to treatment and preventive measures. The law requires that all such information obtained by physicians and health officials be kept confidential.

Until this law was passed, compulsory vaccination was required only for smallpox; it is now required also for typhoid, paratyphoid, whooping cough, tuberculosis, and diphtheria. According to Dr. Ira D. Hirsch of the Preventive Medicine Division, Supreme Command, American Forces in the Pacific, through the provisions of this law the public health standards for the Japanese people will be greatly improved.

CORRECTIONS

Diabetes.—In THE JOURNAL of July 24, page 1172, in the review of the book "Diabetes and the Diabetic in the Community," the primary purpose of the book was misstated. The author states in the preface that the book was written primarily for the teaching of the patient in the community rather than for the nursing of the patient in the hospital.

Acute Renal Insufficiency.—In the article entitled "Severe Acute Renal Insufficiency with Recovery" by Muirhead and Fromm in the August 14 JOURNAL, page 1378, the caption for figure 1 belongs to figure 4 and the caption for figure 4 belongs to figure 1. Also in the properly placed caption for figure 4 the term "unbroken line" is used twice. Actually here "unbroken line" represents blood urea (milligrams per hundred cubic centimeters) and "broken line" represents urine urea (grams).

Deaths

Charles Frederick Williams † professor emeritus of psychiatry at the Medical College of the State of South Carolina, died at his home in Columbia, S. C., June 3, aged 72, of coronary occlusion. Dr. Williams was born in York County, S. C., Aug. 6, 1875. After graduation from the University of Maryland School of Medicine in Baltimore in 1899, he first practiced in York, and then, on March 4, 1901, became acting assistant surgeon in the U. S. Army, serving in Georgia and in the Philippines. On March 4, 1903, Dr. Williams resigned from the army, took postgraduate work in Baltimore; in July 1903, he began general practice in Columbia, where he served as city physician. He was secretary of the state board of health in 1907 and in 1908 became South Carolina's first state health officer, resigning in 1911 to take postgraduate work in Europe. In 1910 he was vice chairman of the Section on Preventive Medicine of the American Medical Association. Dr. Williams was a specialist certified by the American Board of Psychiatry and Neurology, past president of the Columbia Medical Society, South Carolina Hospital Association, American Psychiatric Association and South Carolina Conference on Social Work. He was one of the organizers and a director of the South Carolina Society for Mental Hygiene, a director of the Richland County Mental Hygiene Society and a director of the National Committee for Mental Hygiene. He was one of the organizers, a member of the executive committee and a director of the Columbia Chapter of the American Red Cross, and a delegate to the International Convention of Rotarians at Vienna, Austria, in 1931. In 1915, he was appointed a member of the board of regents of the South Carolina State Hospital, where he was superintendent from 1915 to 1945; he then resigned to become director of the hospital's research activities. In 1942 he became a trustee of the Ensor Research Foundation. The University of South Carolina conferred on him the degree of doctor of laws and awarded him the Algernon Sydney Sullivan Medal for unselfish service.

Philip Weatherly Huntington † Colonel, U. S. Army, retired, Bradenton, Fla.; born in Connecticut Jan. 20, 1876; Columbian University Medical Department, Washington, D. C., 1898; Army Medical School in 1903, Medical Field Service School, advanced course, in 1927; entered the regular army as an assistant surgeon in 1902; promoted through the various grades to that of colonel in October 1928; served overseas during World War I and was awarded the Silver Star and Purple Heart; formerly commandant at the Army Medical School and Army Medical Center in Washington, D. C.; retired for age by operation of law Jan. 31, 1940; recalled to active duty and served during World War II; retirement changed to disability in line of duty Aug. 6, 1945; professor of military science and tactics at his alma mater; fellow of the American College of Surgeons; died May 12, aged 72, of heart disease.

Olga R. Povitzky, New York; born Dec. 25, 1877; Woman's Medical College of Pennsylvania, Philadelphia, 1901; for many years research bacteriologist with the New York City Department of Hospitals; during World War I served in France with the hospital unit of the New York Infirmary; member of the New York Academy of Medicine, the Woman's Medical Association, American Association of Immunologists; Society of American Bacteriologists and the American Public Health Association; formerly connected with bacteriologic research at Mount Sinai Hospital and the gynecologic and medical clinics of the New York Infirmary for Women and Children; died at Moores Mill, N. Y., May 21, aged 70, of leukemia, coronary thrombosis and diabetes mellitus.

Lewis George Allen † Kansas City, Kan.; born in Lenexa, Kan., in 1891; University of Kansas School of Medicine, Kansas City, Kan., 1917; professor of clinical radiology at his alma mater; specialist certified by the American Board of Radiology; past president of the Radiological Society of North America, Kansas City Southwest Clinical Society, Wyandotte County Medical Society and the Kansas City Radiological Society; fellow of the American College of Physicians; chancellor of the American College of Radiology; member of the American Roentgen Ray Society; served during World War I; on the staffs of Bethany Hospital, St. Margaret's Hospital and Providence Hospital, where he died May 28, aged 57, of myelogenous leukemia.

William Joseph Leahy † Ansonia, Conn.; born in Ansonia, Oct. 23, 1876; College of Physicians and Surgeons, Baltimore, 1899; member of the West Virginia State Medical Association; at one time practiced in Mannington, W. Va., where he was president of the Marion County Medical Society, health officer and president of the chamber of commerce; served in the medi-

cal corps of the U. S. Army during World War I; died in the New Haven (Conn.) Hospital May 31, aged 71, of cardiac infarct, pulmonary embolus and arteriosclerosis.

Achilles S. Abshire, Beckley, W. Va.; Baltimore Medical College, 1891; died in the Raleigh General Hospital May 30, aged 87, of heart disease.

Roy M. Armstrong, Franklin, Ky.; Hospital Medical College, Eclectic, Atlanta, 1911; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; affiliated with St. Joseph and Good Samaritan hospitals in Lexington; died May 3, aged 64, of coronary occlusion.

Henry Barnes † New Bedford, Mass.; Columbia University College of Physicians and Surgeons, New York, 1903; veteran of the Spanish-American War; on the courtesy staff of St. Luke's Hospital; chief of staff at Acushnet Hospital; died May 29, aged 70, of lymphosarcoma of the ileum.

William A. Boies, Knoxville, Tenn.; New York Homeopathic Medical College and Hospital, New York, 1896; member of the American Medical Association; affiliated with St. Mary's and Fort Sanders hospitals; died June 5, aged 77, of coronary thrombosis.

Raymond Bernard Benning † Fort Recovery, Ohio; Northwestern University Medical School, Chicago, 1936; on the staff of the Gibbons Hospital, where he died May 21, aged 39, of coronary thrombosis.

John L. Bosworth † Elkins, W. Va.; College of Physicians and Surgeons, Baltimore, 1889; an Affiliate Fellow of the American Medical Association; served as president of the board of education of the Huttonsville District, and as a member of the board of education of Randolph County for six years; died May 14, aged 91, of senility.

William K. Detwiler, Bellevue, Wash.; New York Homeopathic Medical College and Hospital, New York, 1893; died in the Virginia Mason Hospital, Seattle, May 12, aged 77, of coronary thrombosis.

Fred Eugene Earle, Weeks Mills, Maine; Medical School of Maine, Portland, 1900; member of the American Medical Association; died in China April 22, aged 76, of coronary thrombosis.

John Wesley Eckman Jr., Winchester, Ill.; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1908; affiliated with Passavant Memorial Hospital and Our Saviour's Hospital, in Jacksonville, where he died May 11, aged 66, of cirrhosis of the liver.

David Ellner, New York; Medico-Chirurgical College of Philadelphia, 1916; died March 10, aged 61, of cerebrovascular accident and arteriosclerosis.

Prewitt LaFayette Hagler, Birmingham, Ala.; Medical College of Alabama, Mobile, 1891; affiliated with the West End Branch of Baptist Hospital and the South Highland Infirmary; died in Jefferson Hospital May 3, aged 81, of uremia.

George B. Hamlin, Minneapolis; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1896; member of the American Medical Association; served the faculty of his alma mater; affiliated with Maternity and St. Barnabas hospitals; died May 2, aged 77, of coronary disease.

Stuart Van Rensselaer Hooker, Seattle; Harvard Medical School, Boston, 1902; member of the American Medical Association; fellow of the American College of Surgeons; died May 20, aged 74, of coronary thrombosis.

Chester James Hurlbut, Lake Wales, Fla.; University of Vermont College of Medicine, Burlington, 1899; for many years superintendent of the Bartow General Hospital in Bartow; died May 3, aged 74, of diabetes mellitus and cerebral hemorrhage.

James Beauregard Jarvis, Laurel, Miss.; Memphis (Tenn.) Hospital Medical College, 1893; member of the American Medical Association; died May 31, aged 87, of heart disease.

Fred Johnson † Eau Claire, Wis.; Wisconsin College of Physicians and Surgeons, 1904; died April 30, aged 76, of cerebral hemorrhage and arteriosclerosis.

Walter Gambol Johnson, Childress, Texas; University of Tennessee Medical Department, Nashville, 1900; died in Childress General Hospital May 17, aged 70, of cerebral hemorrhage.

William Arthur Jones, Morton, Miss.; Mississippi Medical College, Meridian, 1911; died May 2, aged 70, of arteriosclerosis.

Israel J. K. Light, Reading, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the American Medical Association; died in the Good Samaritan

Hospital, Lebanon, April 23, aged 75, of malignant prostatic hypertrophy.

John Joseph Williams Looney * Rocky Mount, N. C.; University of Virginia Department of Medicine, Charlottesville, 1909; went to the Mayo Clinic, Rochester, Minn., in September 1914 as an assistant in the department of ophthalmology and left the clinic in July 1918; on the staff of the Park View Hospital; died May 12, aged 68, of cerebral hemorrhage.

Raymond Stanley Love, Whiting, Kan.; Northwestern University Medical School, Chicago, 1909; died in Muscatine, Iowa, April 13, aged 64, of coronary thrombosis.

Henry Lubinsky * Fall River, Mass.; Tufts College Medical School, Boston, 1927; medical examiner for a draft board during World War II; chief of pediatrics at Fall River General and St. Anne's hospitals; on the staff of Union Hospital; died May 25, aged 45, of cerebral hemorrhage.

Eugene Hartwell Luck * Roanoke, Va.; Medical College of Virginia, Richmond, 1912; died in the Lewis-Gale Hospital May 10, aged 62, of cerebral hemorrhage.

Arthur Norton Mackey, Chicago; Medical College of Indiana, Indianapolis, 1891; died June 6, aged 80, of chronic myocarditis and arteriosclerosis.

Robert Morris Marshall, San Antonio, Texas; Colorado School of Medicine, Boulder, 1903; died May 1, aged 79, of cardiac decompensation.

John Wallace McCollom, Portland, Ore.; University of Oregon Medical School, Portland, 1908; member of the American Medical Association; served during World War I; affiliated with the Good Samaritan Hospital, where he died May 26, aged 62, of carcinoma.

Henry Garnsey McCormick, Laurel, Miss.; Rush Medical College, Chicago, 1891; member of the American Medical Association and the American College of Radiology; specialist certified by the American Board of Radiology; died May 23, aged 80, of cerebral hemorrhage.

John Edward McGuiggan, Chicago; Chicago College of Medicine and Surgery, 1915; member of the American Medical Association; served during World War I; affiliated with Evangelical Hospital and St. George's Hospital, where he died May 30, aged 56, of coronary thrombosis.

Charles M. McNaull * Indianapolis; Bellevue Hospital Medical College, New York, 1891; on the staffs of the General, Methodist and St. Vincent's hospitals; died May 16, aged 84, of coronary occlusion.

George Harris Merryman * Klamath Falls, Ore.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; affiliated with Hillside Hospital; died May 6, aged 69, of coronary heart disease.

William Glassell Miller Jr., Freeport, N. Y.; Long Island College Hospital, Brooklyn, 1908; also an attorney; formerly member of the Nassau County Mosquito Extermination Commission and director of the First National Bank; died May 27, aged 69, of coronary occlusion.

Robert Edward Alexander Milne, Le Roy, N. Y.; University of Toronto Faculty of Medicine, 1925; member of the American Medical Association; served as a member of the board of education; during World War II a major in the medical corps of the U. S. Army Air Forces in the Mediterranean theater; on the staff of the Genesee Memorial Hospital, Batavia; died in Strong Memorial Hospital, Rochester, May 4, aged 48, of carcinoma.

John George Mollath, White Plains, N. Y.; Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg, Germany, 1891; died April 10, aged 80, of diabetes mellitus and arteriosclerosis.

Alexander Harris Moody, Dyersburg, Tenn.; Memphis (Tenn.) Hospital Medical College, 1903; served as county health physician; on the staff of the Baird Brewer Hospital; died May 9, aged 68, of carcinoma of the sigmoid colon.

Tarleton Flemming Moore, Hot Springs National Park; Ark.; University of Texas School of Medicine, Galveston, 1908; served overseas during World War I; formerly associated with the U. S. Public Health Service Reserve and with the Veterans Administration, having been in charge of its hospital in Alexandria, La., and on the staffs of various other administration hospitals; died May 28, aged 63, of carcinoma of the palate.

Frank Henry Mowe, Leominster, Mass.; Dartmouth Medical School, Hanover, N. H., 1888; died April 26, aged 84, of uremia.

Frank Leo Mozdy, Erie, Pa.; University of Cincinnati College of Medicine, 1936; served overseas during World War

II; on the staffs of St. Vincent's and Hamot hospitals; died May 8, aged 40, of coronary thrombosis.

George L. Mueller, St. Louis; St. Louis College of Physicians and Surgeons, 1890; died in Barnes Hospital May 3, aged 79, of hypertensive cardiovascular renal disease.

Joseph Timothy Murphy * Pottsville, Pa.; Jefferson Medical College of Philadelphia, 1913; attached to the 103rd Engineers with the rank of captain during World War I; one of the founders, staff member and a member of the hospital board of the Lemos B. Warne Hospital, where he died May 17, aged 58, of cerebral hemorrhage.

Max W. Myer * St. Louis; Marion-Sims College of Medicine, St. Louis, 1899; member of the founders group of the American Board of Surgery; professor of surgery at the St. Louis University School of Medicine; fellow of the American College of Surgeons; served during World War I; affiliated with the Jewish Hospital; died in Clayton, Mo., May 16, aged 70, of heart disease.

Anthony F. Myers, Blooming Glen, Pa.; Missouri Medical College, St. Louis, 1885; member of the American Medical Association; for many years secretary of the Bucks County Medical Society; died in Grand View Hospital, Sellersville, May 6, aged 92, of hypostatic pneumonia and fracture of humerus received in a fall.

Thomas Francis Nolan, New York; Jefferson Medical College of Philadelphia, 1907; died May 27, aged 64, of cerebral hemorrhage.

Thomas Hillman Oliphant * Corpus Christi, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1925; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; died May 31, aged 47.

John Ransom Palmer, Shreveport, La.; Columbia University College of Physicians and Surgeons, New York, 1936; member of the American Medical Association and of the Medical Society of the State of New York; interned at St. Luke's Hospital in New York; served overseas during World War II; died in a hospital at Miami, Fla., May 2, aged 43.

John Dent Peabody, St. Petersburg, Fla.; Long Island College Hospital, Brooklyn, 1881; University of Pennsylvania Department of Medicine, Philadelphia, 1882; member of the American Medical Association; veteran of the Spanish-American War; served on the staff of the Mount Park Hospital; died May 30, aged 88, of pneumonia and arteriosclerosis.

Herbert Leroy Pettitt * Morrison, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; formerly assistant health director of the state department of public health; died May 6, aged 72, of virus pneumonia and coronary occlusion.

Joseph Royal Phelps * Medical Director, Captain, U. S. Navy, retired, Long Beach, Calif.; Harvard Medical School, Boston, 1903; entered the U. S. Navy on July 24, 1908; retired Feb. 1, 1939 on own application after thirty years' service; died in the U. S. Naval Hospital May 8, aged 67, of ruptured aortic aneurysm due to arteriosclerosis.

Charles Bates Phillips * Amsterdam, N. Y.; Albany (N. Y.) Medical College, 1908; past president of the Montgomery County Medical Society; affiliated with the Amsterdam City and St. Mary's hospitals; died May 11, aged 63, of carcinoma of the stomach.

John Ezra Phillips, Ewing, Ill.; St. Louis University School of Medicine, 1903; died May 8, aged 75, of heart disease.

Samuel Plahner, Milwaukee; Medizinische Fakultät der Universität Wien, Vienna, Austria, 1903; member of the American Medical Association and Central Neuropsychiatric Association; served on the staff of the Evangelical Deaconess Hospital; died in the Milwaukee Hospital May 8, aged 70, of acute gastrointestinal hemorrhage.

Rudolph M. Rau * Frederick, Md.; College of Physicians and Surgeons, Baltimore, 1893; died May 26, aged 76, of cerebral hemorrhage.

John Augustus Riebel * Columbus, Ohio; Ohio Medical University, Columbus, 1901; in 1940 received the honorary degree of doctor of laws from Capital University; on the staffs of Mercy Hospital and White Cross Hospital, where he died May 27, aged 78, of cerebral hemorrhage.

Rose Sylvia Rubin * Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1910; served on the boards of education and health; on the staff of Mount Sinai and Women's hospitals; died May 16, aged 68, of carcinoma.

John Edward Ruisi * Westerly, R. I.; Tufts College Medical School, Boston, 1917; fellow of the American College of Surgeons; medical officer for the U. S. Coast Guard since 1930;

served during World War I; member of the International College of Surgeons; consulting surgeon at the Homeopathic and St. Joseph's hospitals in Providence and South County Hospital, Wakefield; senior surgeon at Westerly Hospital; died May 27, aged 56, of carcinoma of the right kidney.

Nicholas Alexander Rumanceff, Brooklyn; University of Moscow Faculty of Medicine, Russia, 1899; since 1926 assistant pathologist at Kings County Hospital; died May 21, aged 73, of cerebral hemorrhage.

Arthur Jemmott Sayers, Yonkers, N. Y.; Howard University College of Medicine, Washington, D. C., 1929; served on the staff of the Lincoln Hospital in New York, where he died April 11, aged 54, of cerebral thrombosis.

August Henry Schade † Toledo, Ohio; Toledo Medical College, 1908; for many years secretary-treasurer of the Ohio Society of Pathologists; charter member of the American Society of Clinical Pathologists; served during World War I; on the staff of the Robinwood Hospital; died May 15, aged 63, of pulmonary edema.

Joseph John Schill † Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1904; a medical examiner for draft boards during World wars I and II; on the courtesy staff of St. Francis Hospital, where he died May 8, aged 70, of arteriosclerotic heart disease.

Harry Leach Schurmeier † Santa Barbara, Calif.; Northwestern University Medical School, Chicago, 1911; member of the American Association for the Surgery of Trauma; served in France during World War I; died May 11, aged 64, of coronary thrombosis.

Walter Edgar Scott, Adel, Iowa; Drake University College of Medicine, Des Moines, 1891; at one time on the faculty of his alma mater; member of the American Medical Association; served as a member of the board of education; died in Des Moines May 21, aged 83, of cardiac compensation.

Newton Loomis Sebastian, Pass Christian, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1924; member of the American Medical Association and of the Louisiana State Medical Society; served in the U. S. Naval Reserve during World War II; died in the Memorial Hospital, Gulfport, May 7, aged 47, of uremia.

William Alvin Sickels † South Milwaukee, Wis.; Detroit College of Medicine, 1896; served during World War I; died May 19, aged 77, of coronary occlusion.

Maurice L. Silberman, New York; Medical College of Virginia, Richmond, 1911; member of the American Medical Association; died May 5, aged 65, of coronary thrombosis.

Caroline B. Skinner, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1897; for many years on the staff of Deaconess Hospital; died June 7, aged 90, of senility.

Lotus Mast Slabaugh, Nappanee, Ind.; Hahnemann Medical College and Hospital of Philadelphia, 1928; member of the American Medical Association; local health officer; affiliated with the Elkhart (Ind.) General Hospital, where he died May 21, aged 46, of coronary occlusion.

George Ritter Smith † Seattle; John A. Creighton Medical College, Omaha, 1909; member of the Idaho State Medical Association and the American Psychiatric Association; at one time state director of public health in Idaho; formerly superintendent of Nevada State Hospital in Reno, and medical superintendent of the State Hospital, South, Blackfoot, Idaho; served as senior psychiatrist at the Northern State Hospital, Sedro Woolley, Wash.; died in Swedish Hospital May 15, aged 62, of aneurysm.

William Polson Smith, Columbus, Mont.; University of Illinois College of Medicine, Chicago, 1909; member of the American Medical Association and the International College of Surgeons; past president of the Montana State Medical Association and the Montana Public Health Association; served as a major in the medical corps of the Army of the United States during World War II; died in Beehive May 4, aged 66, of coronary occlusion.

Joseph Nelson St. Denis, Boston; Baltimore University School of Medicine, 1892; member of the American Medical Association; died May 20, aged 82, of arteriosclerosis.

Timothy Joseph Sullivan, Washington, D. C.; Georgetown University School of Medicine, Washington, 1904; died in St. Elizabeth's Hospital May 26, aged 74, of lobar pneumonia.

John Richardson Thompson, Bridgeport, Ill.; Hospital College of Medicine, Louisville, Ky., 1902; member of the American Medical Association; formerly county coroner; for many years member of the Illinois General Assembly; died May 14, aged 70, of coronary thrombosis.

John George Vaughan † New York; Northwestern University Medical School, Chicago, 1907; studied at London School of Medicine; director of the Associated Mission Medical Office; formerly medical missionary in China; died in White Plains (N. Y.) Hospital, May 17, aged 70, of coronary thrombosis.

Calvin Albert Walker † San Francisco; Cooper Medical College, San Francisco, 1905; fellow of the American College of Surgeons; served during World War I; past president of the Western Association of Industrial Physicians and Surgeons and vice president of the Congress of Railway Surgeons; chief surgeon for the Southern Pacific General Hospital; on the staff of St. Francis Hospital; died May 18, aged 73.

Clarence Kraus Weil † Montgomery, Ala.; Columbia University College of Physicians and Surgeons, New York, 1923; specialist certified by the American Board of Internal Medicine; member of the American Association for the Study of Allergy; served during World Wars I and II; died May 5, aged 47, of coronary thrombosis.

Stephen Whitaker Wells, Liberty, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1896; member of the American Medical Association; formerly mayor, fire chief and coroner; died May 21, aged 72, of cerebral embolus and coronary occlusion.

Jacob Hial West, Champaign, Ill.; Cooper Medical College, San Francisco, 1894; died in the Memorial Hospital, Springfield, May 1, aged 81.

Edward Claude Westaver, St. Louis; St. Louis College of Physicians and Surgeons, 1918; died May 20, aged 66, of cerebral hemorrhage.

Frank Robert Wheelock † Scranton, Pa.; Harvard Medical School, Boston, 1905; member of the American College of Chest Physicians; served as director of public health; veteran of the Spanish-American War; received decorations from the French and U. S. governments for service during World War I; formerly medical director of Lackawanna County Tuberculosis Hospital; died May 12, aged 69.

Walter Burleigh Whipple, Peoria, Ill.; Chicago College of Medicine and Surgery, Chicago, 1904; died in the Proctor Hospital April 25, aged 65.

William G. White, Centralia, Mo.; St. Louis College of Physicians and Surgeons, 1892; Barnes Medical College, St. Louis, 1896; served overseas during World War I; died in Audrain County Hospital, Mexico, May 1, aged 79, of arteriosclerosis.

Spencer Draper Whiting, Scottsdale, Ariz.; Boston University School of Medicine, 1905; member of the American Medical Association; served during World War I; formerly associated with the Indian Service; certified by the National Board of Medical Examiners; died in the Veterans Administration Hospital April 29, aged 68, of lung abscess and subacute bacterial endocarditis.

Earl Willbre Williamson, Evanston, Ill.; University of Illinois College of Medicine, Chicago, 1919; assistant director of the American College of Surgeons; member of the advisory council to the program on hospital administration at Northwestern University; died May 10, enroute home from a medical meeting, aged 62, of heart disease.

William Edward Wilmerding † Lieutenant Colonel, U. S. Army, retired, Skyland, N. C.; University of the South Medical Department, Sewanee, Tenn., 1899; Medical Field Service School in 1921 and School of Aviation Medicine in 1923; entered the medical corps of the U. S. Army as major in July 1920; retired Feb. 28, 1938; served during World War I; died in Washington, D. C., May 8, aged 74, of benign hypertrophy of the prostate and hydronephrosis.

Walter Scott Wilson, Savannah, Ga.; Johns Hopkins University School of Medicine, Baltimore, 1904; member of the American Medical Association; served on the local board of education; died May 27, aged 90, of myocardial failure.

William Emanuel Yount, Cape Girardeau, Mo.; Vanderbilt University School of Medicine, Nashville, Tenn., 1898; specialist certified by the American Board of Ophthalmology; member of the American Medical Association; died April 6, aged 74, of coronary disease.

Ross Luverne Zimmerman † Detroit; Detroit College of Medicine and Surgery, 1915; died in Mount Carmel Mercy Hospital May 23, aged 62, of cerebral thrombosis.

George Guido Zohrlaut, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; member of the American Medical Association; died June 9, aged 69, of carcinoma of the bladder.

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 24, 1948.

Difficulties of the National Health Service

Mr. Bevan, the socialist Minister of Health, has said that his object is to take money out of the doctor-patient relation, so that the poorest can obtain without payment all the medical attention that he requires, including that of the highest specialist. But difficulties have already arisen in the attainment of this deal. In the House of Commons a socialist member complained that a minority of physicians were creating a medical black market in order to obtain more money at the expense of the community. They were refusing to take on their lists persons believed to be sufficiently well off to pay high fees. Worse than this, there were physicians who refused patients because they needed extra attention. The old, the sick and the children were refused for this reason. In 1 case a man was taken but his wife was refused because she had cancer. In a more subtle form the refusal was not outright. The physician said "I will take you if you wish, but you will not get the same attention as you used to. I cannot give you the same as the paying patients, and you must come to the side entrance like the tradesmen."

In reply the Minister of Health said that the practices described were carried on by a small minority of the physicians. The vast majority were playing the game. The transition on July 5 was carried out with remarkable smoothness, impossible in any other country. A physician's selection of some members of a family and refusing another because he was a sick man was reprehensible and cut across the conception of the family doctor. The scales of remuneration for the profession were drawn up on the assumption that all the population might be in the scheme. So generous were the standards of remuneration that 99 per cent of the population would have lower incomes than the general practitioners. Where doctors were saying that a potential patient could afford to pay they were in most cases saying it to persons whose incomes were less than their own. Certain sanctions could be applied. Areas where physicians said that they were unable to take patients on their lists but insisted on their remaining private patients should be regarded as underdoctored. This means that the government could use inducements to settlements of physicians in that area. Further, it was obligatory on the physician to provide adequate facilities for his patients and it was not proper for him to provide superior facilities for his private as against his public patients.

The Minister is correct in his boast that the transition from private to socialist practice of medicine has been carried out with remarkable smoothness. But it has to be remembered the latter already existed in the panel system, which applied to the majority of wage earners but not to their wives and children or to those whose incomes were above a certain level. Also the transition has been at a time when illness is at a minimum. The test of the new system will come with the colder weather and the epidemics, from which we are usually free at this time of year.

Surgery Versus Radiotherapy in Carcinoma of the Cervix

At the Edinburgh Obstetrical Society Mr. Charles Read opened a discussion on the relative merits of surgery and radiotherapy in carcinoma of the cervix. He said that there was a division of opinion in regard to stages 1 and 2 but little debate in respect to stages 3 and 4, which were generally unsuitable for surgery. In many clinics the Wertheim operation was abandoned when radiotherapy was generally established, but at the Chelsea Hospital for Women it had been performed

continuously since Mr. Bonney introduced it in 1907. Even the surgical enthusiast had to admit that the results of radiotherapy compared favorably with those of surgery, but the question might be raised whether some of the fatalities after radiotherapy could be avoided by judicious surgery. Mr. Read suggested that there were seven indications for surgery in carcinoma of the cervix: (1) radioresistant growths proved either clinically or cytologically; (2) columnar-celled carcinoma; (3) vaginal vault stenosis; (4) the presence in addition of large fibroids or ovarian cysts; (5) associated salpingitis; (6) refusal of irradiation by the patient, and (7) pregnancy in the presence of cervical carcinoma. Considering the Wertheim operation after previous irradiation, Mr. Read expressed the opinion that although this did increase the technical difficulties the operation was justifiable in radioresistant cases, experience at the Chelsea Hospital showing a five year survival rate of 44.4 per cent in 34 stage 1 and 20 stage 2 growths.

Games for the Paralyzed

Since the war rehabilitation of the disabled has received much attention in this country. At the Ministry of Pensions Hospital, established for this purpose, a remarkable demonstration of what can be done for those suffering from spinal paralysis has been given by an archery tournament between two teams, who shot their arrows with surprising accuracy. Mr. H. A. Marquand, the Minister of Pensions, was present and said that his department was striving to bring the pensioner back as far as was possible into the normal life of the community. He was pleased to say that more than 80 per cent were employed.

Dr. L. Guttman, director of the head and spinal injuries section of the hospital, stated that it had been proved beyond doubt that many games, such as darts, billiards, snooker, skittles, badminton, net ball and even polo, can be adjusted to the disability of paralyzed persons, enabling them to compete successfully with normal persons. He had chosen archery as the most suitable sport, with the possible exception of swimming, for the paralyzed, because it had great therapeutic value.

The Wartime Behavior of Graves's Disease

A recent investigation by Dr. Kurt Iversen (Rosenskilde and Bagger, 1948) has brought out some curious facts concerning the behavior of Graves's disease in Denmark during the German occupation. There had been a fairly uniform rise in the incidence of this disease since 1931, but it was not till 1942 that this rise became really striking. Dr. Iversen's material consists of 2,802 patients with recently diagnosed disease admitted to the municipal hospitals of Copenhagen between the beginning of 1938 and the end of 1945. The rise in the period 1941 to 1944, inclusive, was followed by a decided fall in 1945, and the rise cannot, apparently, be explained away by reference to the growth of population, an increase in the hospital admission rate or more accurate diagnoses in the period under review.

It is, of course, tempting to associate this rise in the frequency of Graves's disease with the nervous strain entailed by the German occupation. But Dr. Iversen finds that psychic trauma could be held responsible for the onset of the disease in barely 5 per cent if one is to be guided by hospital records. Besides, it was not till 1944 and 1945 that the Danish reaction to the Germans assumed violent proportions, and by then the rise in Graves's disease had already culminated. It is also curious in this connection that in German-occupied Norway a rise in the frequency of Graves's disease in 1941 was followed by a definite fall in 1942 and the succeeding years in spite of the growing violence of the Norwegian opposition to the Germans. Then

again, in the period 1939 to 1945, there was a definite decline in the incidence of Graves's disease in German-occupied Holland and Belgium. Dr. Iversen suggests that the key to this problem may possibly be found in the lack of certain elements in the wartime dietary of Denmark, whose supply of margarine derived from the soya bean was cut off in 1941. The bitter cold of the wartime winters may also have played a part, but Dr. Iversen is wisely and cautiously tentative in his correlation of possible causes with effects.

Epidemic Diseases in Denmark in 1947

The returns published by the Danish public health authorities concerning the incidence of the epidemic diseases from year to year make stimulating reading, for in many instances they suggest questions instead of supplying answers. Let us take the incidence of some of these diseases in 1947 and compare it with the "normal," i. e., the average for several years up to 1940. And then let us ask ourselves to explain the decided difference in many cases between the two figures.

	1947	"Normal"
Typhoid.....	84	40
Epidemic cerebrospinal meningitis.....	422	65
Diphtheria.....	413	1,350
Scarlatina.....	5,138	9,300
Puerperal fever.....	108	210
Measles.....	21,320	2,700
Mumps.....	28,603	3,450
Angina tonsillaris.....	137,250	95,000
Bronchopneumonia.....	31,089	22,570
Croupous pneumonia.....	6,409	3,700
Acute infectious gastroenteritis.....	59,278	33,400
Acute epidemic hepatitis.....	9,122	2,800
Gonorrhea.....	15,267	8,250
Acquired syphilis.....	2,301	315

Note that the "normal" for the venereal diseases refers only to 1940 and not to any previous years.

This table might well figure in an examination paper set for senior medical students asked to explain in each case why the figure for 1947 differs so greatly from the "normal." The answer in the case of gonorrhea and syphilis is easy and monosyllabic—war. Perhaps the same answer is valid for typhoid. But what of the gigantic rise in the incidence of mumps and acute epidemic hepatitis? And can we flatter ourselves that the decline in the diphtheria rate reflects the success of our vaccination against it? The examinee who can explain the rise or fall of the disease in every case must be a happy blend of Hippocrates and Baron Munchausen.

Hospital Accommodation for the Aged Sick

In 1942 Professor Meulengracht drew attention to the overcrowding of the general hospitals with the aged sick, and now Dr. H. G. Davidsen has returned to the charge with a statistical analysis of the age distribution of the patients treated in the medical department of a certain Danish hospital. For, be it noted, it is the medical rather than the surgical side of a general hospital which suffers in this respect. Dr. Davidsen's analysis of the years 1930 and 1945 shows that in the interval between these two years the average duration of stay in hospital per patient has been shortened considerably, and this phenomenon is most obvious in the case of young patients, probably, and to a large extent, because of the effectiveness of the sulfonamide group of drugs. This brisk circulation of comparatively young patients means that three or four of them can be treated for every elderly patient. While the cost per bed per day on the medical side of a general hospital is kr. 25, it is only kr. 9.60 in public hostels for the aged.

Dr. Davidsen asks in effect: What good does twenty-five days' sojourn in a costly general hospital do for the aged infirm who need prolonged care not necessarily entailing the costly equipment and staffing of a general hospital? Dr. Davidsen shows that between 1930 and 1945 the number of persons over the age of 65 in Copenhagen rose from 43,000 to 62,000, and even when account is taken of the general rise of the population in the same period, this rise in the number of the aged is

impressive. He calculates that the need for institutional treatment for the aged will continue to rise till 1980 at any rate. He has set himself three aims: (1) to relieve the congestion of the general hospitals; (2) to provide the aged with medical care and nursing of good quality, and (3) to do so without waste of public funds.

RIO DE JANEIRO, July 25, 1948.

Oral BCG Vaccination of Newborn Infants

Dr. Ariundo de Assis has published a report on the work of the Ataulpho de Paiva Tuberculosis Foundation during 1947, when 20,516 newborn infants were vaccinated on the fourth to the tenth day of life with a single dose of 100 mg. of BCG by mouth. The immunization by this method was as well tolerated as the former system of giving three doses of 30 mg. on alternate days to every infant. From the point of view of mass vaccination of newborn infants the single dose method is clearly more advantageous than the former one. The BCG vaccine used was prepared with 14 day old pellicle growths and the fluid employed was the Sauton diluted to one-fourth strength and carefully adjusted to pH 7.2. The concentration of BCG in the vaccine was 20 mg. per cubic centimeter, the vaccine having been stored at 4 C. for no longer than ten days after its preparation. To determine the first appearance of tuberculin reactivity of vaccinated children living in nontuberculous households, a sample of 2,028 infants was tested intradermally with 1 mg. and 10 mg. of old tuberculin. Reactions were considered positive only if the indurations reached more than 4 mm. in diameter after forty-eight hours. About 60 per cent of reactors were observed between the fourth and the sixth week of life of the vaccinated. The Negro infants were more particularly able to become tuberculin positive than the white. Starting from the seventh week of life an increasingly larger proportion of reactors was found. Dr. Assis expressed the belief that the single dose method of immunizing newborn infants may represent a decided step toward a final extensive program of tuberculosis prevention.

A New Culture Medium for Trypanosoma Cruzi

Drs. Gilberto de Freitas and Firmino T. Castro, of the Oswaldo Cruz Institute, Rio de Janeiro, succeeded in the preparation of a culture medium for the causative agent of American trypanosomiasis that represents a decided improvement. Starting from the hypothesis that the blood components which are responsible for the growth of flagellates in culture mediums are not proteins but less complex substances, Freitas and Castro tried the enzymatic hydrolysis of total blood, aiming at the definitive elimination of any material that may be precipitated, as well as the elimination of any growth factor eventually connected with the protein molecule. They were able to prepare a culture medium free from cells and particles and of coagulable proteins and permitting the sterilization by autoclave. Twenty-five successive subcultures were obtained without any sign of decrease of the multiplication capacity of the organism. Some preliminary counts revealed 8,000,000 organisms per cubic centimeter in tubes with 4 cc. of medium and inoculated with 25 per cent of a culture. With larger inoculums about 12,000,000 organisms per cubic centimeter can be obtained in flasks with 100 cc. of medium. The culture can be made in tubes for conservation of the samples, or in Erlenmeyer flasks for large scale production.

Personal

Dr. Achilles de Araujo was appointed professor of orthopedy and traumatology at the University of Rio de Janeiro.—Dr. Josias de Freitas was appointed assistant professor of surgery at the University of Rio de Janeiro.

Correspondence

PRESIDENTS OF THE A. M. A.

To the Editor:—I have been interested in compiling a statistical analysis of the educational background of the Presidents of the American Medical Association during the first one hundred years of its existence. From "A History of the American Medical Association" by Fishbein, I have compiled the following data relative to the medical schools from which the various Presidents of the American Medical Association were graduated. The University of Pennsylvania leads in the number of graduates, twenty of the Presidents of the American Medical Association having received their degrees in medicine from that institution. Harvard comes second with ten graduates, followed by the College of Physicians and Surgeons in New York with seven and Jefferson Medical College with six. Northwestern Medical College, Bellevue Hospital Medical College, Rush Medical College and the University of Louisville each graduated four subsequent Presidents of the American Medical Association. The remaining Presidents were graduated from thirty-three other schools of medicine. Several of these are now extinct, and several others have merged with other educational institutions. It is of interest to note that two of the Presidents of the American Medical Association graduated from the Medical School of the University of Edinburgh, while one President received his degree at the University of Bonn in Germany.

M. LOWRY ALLIN, M.D., Salt Lake City.

TREATMENT OF ASTHMA

To the Editor:—In the panel discussion of the "Treatment of Asthma" in THE JOURNAL, May 29, 1948, statements were made by Dr. Piness concerning penicillin aerosol which need to be corrected. It is my belief that penicillin aerosol is of definite value in the treatment of infective asthma, which need not necessarily be limited to the complications of bronchiectasis or pulmonary abscesses. This opinion is based on extensive use of aerosol therapy for three years, in the treatment of respiratory infections including infective asthma. Allergists who deny the usefulness of this method of treatment have either attempted to treat asthma of the noninfective type in which penicillin is definitely contraindicated and have, therefore, had failures, or given penicillin aerosol during an attack of asthma when the vital capacity is so reduced that the aerosol is not effectively inhaled.

Once a decision has been made to treat with penicillin aerosol, it is important to administer this aerosol only after preliminary bronchodilatation, to obtain maximum utilization. In our experience, this can be achieved by the inhalation of aminophyllin in aerosol form as produced by a combined steam generator and aerosolizer previously described in THE JOURNAL, and which has been a simple and inexpensive means of producing a variety of aerosols without the need of costly oxygen.¹ The steam itself administered to these patients has, in some instances, therapeutic value.

Another reason for repeated reports of failures has been, in my opinion, the inability to produce aerosols of long duration. Aqueous aerosols of penicillin do not "live" long enough to be effectively utilized. An aerosol produced, however, of penicillin dissolved in propylene glycol can last an hour under certain conditions, which has not only increased its efficiency but has enabled us to utilize a tent, a breathing box and a closed chamber

(the bathroom at home) for the maximum utilization of the aerosol, in the treatment of sinorespiratory infections.²

Not all cases of truly infective asthma respond favorably to penicillin aerosol—the type of organism concerned must be penicillin sensitive, and adequate dosage must be given. Nevertheless, so many patients do respond favorably as to make this a major form of therapy. As for the unfavorable reactions referred to by Dr. Piness, in our experience these have occurred in less than 10 patients of over 300 treated. In only 1 of these patients did a severe reaction develop—giant urticaria with joint involvement. The majority were mild urticarias or contact dermatitis. "Black tongue" reactions were not encountered in these cases.

SAMUEL J. PRIGAL, M.D.,

New York.

HYPERTENSION

To the Editor:—The concept of the pathogenesis of hypertension editorially reviewed in THE JOURNAL, May 10, 1948, however attractive from a clinical aspect, rests, unfortunately, on a tenuous chain of demonstrations. Among the experiments on which Heinbecker's new and elaborate concept is based, two facts seem to have been confirmed and to withstand critical appraisal: (1) neurohypophyseal deficiency resulting from total or partial denervation of the gland and (2) nephrotoxic and vascular lesions due to desoxycorticosterone. On the other hand, seven bases for the concept have not yet had adequate experimental support: (1) that posthypophyseal deficiency stimulates the eosinophils of the pars distalis, (2) that specific cardiotropic and nephrotrophic effects may be ascribed to the eosinophils, (3) that adrenocorticotropin induces the secretion of desoxycorticosterone-like compounds, (4) that deficiency of the posthypophysis sensitizes to pressor agents, (5) that desoxycorticosterone causes a constriction of the efferent glomerular arterioles, (6) that the efferent arteriolar vasoconstriction leads to liberation of renin and (7) that renin is the cause of hypertension.

The concept reviewed is an expansion of that of Selye (*J. Clin. Endocrinol.* 6:117, 1946), which deals with anterior pituitary, adrenals and kidney. Heinbecker's hypothesis aims at the integration into this pattern of the central nervous system, (cortex, hypothalamic nuclei and neurohypophysis). However, until the premises have been confirmed, the conclusions must remain as thought-provoking speculations only.

Cleveland Clinic Foundation.

MUSCULAR CRAMPS AFTER "MERCUPURIN"

To the Editor:—A word of caution should be sounded relative to the letter by Perry S. MacNeal, M.D., of Philadelphia, concerning the article "Muscular Cramps After 'Mercupurin,'" appearing under Queries and Minor Notes in THE JOURNAL, June 26, page 824.

Dr. MacNeal's splendid suggestions concerning the occurrence of muscular cramps and paresthesias following the use of "mercupurin" are timely. However, he advises the administration of a 10 per cent solution of calcium gluconate intravenously. One must remember that many of the patients receiving "mercupurin" have also been on digitalis administration and the combination of the two may sometimes result in sudden death. Drs. John O. Bower and William E. Robertson of Philadelphia were two of the first physicians to point out the extreme potential danger of sudden death resulting from the administration of calcium intravenously during digitalization.

Bureau of Investigation

KYRON IS INDEBTED TO SCIENCE

All over the United States recently newspapers and magazines have been carrying an advertisement headed "Science Discovers New Easy Way to Lose Fat." A subheading says "New Condensed Food Tablet Reducing Plan Proves Amazing Power to Help Curb Excess Appetite!" Another says "New Condensed Food Tablet Proves Amazing Power to Safely Reduce Fat. Requires No Starvation . . ."

This double-talk refers to a so-called reducing preparation consisting of certain vitamins in one tablet and amino acid and a digestive in another, plus a booklet which the customer presumably is expected to read and follow. A series of menus is offered which, at first, averaged approximately 1,000 calories per day. A later edition of the booklet, however, called for between 1,200 and 1,600 calories per day. The dietary needs of the average sedentary woman are approximately 2,000 calories a day; perhaps the sellers of "Kyron" should stick to the publishing business, rather than selling vitamins and digestive pills.

The advertisements represent that a "tiny food tablet works wonders for fat folks because, when used as directed in the Kyron Reducing Plan, it helps appease excess hunger [Italics ours.—Ed.], and at the same time works to counteract nutritional deficiencies often caused by reducing." The Council on Pharmacy and Chemistry of the American Medical Association recently considered "Kyron" and similar other reducing plans, candies and mixtures. They concluded that such preparations do not constitute scientific methods for the reduction of excess body weight caused by overeating, and that they have no place in scientific medicine, by reason of the fact that they are in the nature of placebos. Included in such a category are the preparations "R.D.X.," "Ayds," "Meltoway" and some others.

The prime movers in the promotion of Kyron are two lawyers and an ex-restaurant owner. They are aided and abetted by a toxicologist and consulting chemist who has given them a testimonial wherein it is stated:

"I proceeded to formulate a low calory diet, a copy of which is attached hereto . . .

"It is my opinion that the diet accompanying the product Kyron would not in and of itself be sufficient to sustain and maintain good health. It is also my opinion that the diet followed in connection with the taking of Kyron tablets will sustain and maintain good health except if followed by persons afflicted with an abnormal condition. Of course, a person afflicted with an abnormal condition should always consult a physician."

Another statement to aid in the promotion was from a so-called "research and testing laboratory." This read in part:

"This is to certify that World-Wide Laboratories, Inc. [now the Continental Pharmaceutical Corporation], distributors of the product Kyron, retained us over six months ago to create a formula consisting of vitamins, minerals and proteins to the extent that the same could be used as a dietary supplement taken in connection with a prescribed diet to be used by persons who desire body weight reduction . . .

"Our research in the field of obesity, which naturally carried us to opinions, statistics and surveys of the leading authorities in the field, left us no conclusion other than that to bring body weight reduction about, a diet must be followed and with that diet the person must replenish the loss of the essential vitamins and minerals in some manner or form . . .

"For your information we have conducted tests by using the product Kyron on rats and the results of our tests were very satisfactory and showed body weight reduction. No ill effects in the conduct, manner, nervous reactions or any other symptoms which might be considered harmful, were found or displayed . . ."

The appropriate governmental agencies have delayed too long the necessary steps to protect the public from being victimized by these purveyors of tablets. Although advertised as wonderful in the reduction of excess body weight, they are merely adjuncts to highly restricted diets.

The Post Office Department has been active in bringing fraud orders against the purveyors of vitamin pills and fancy reducing pills, branding them as a device to obtain money under false

pretenses, thereby using the mails to defraud. Under date of March 11, 1946, the Postmaster General announced that a fraud order had been issued against the Nu-Dyne Company, Inc., Dr. J. Carter Fisk, J. Carter Fisk, M.D., and Dr. J. Carter Fisk, Chief of Staff, and their officers and agents as such. The product was advertised as follows: "Now! You Too Can Reduce This Safe, Doctor's Way! Dr. J. Carter Fisk Will Show You How to Lose 15 lbs in 7 weeks With the Doctor's Own Proven Safe Reducing Plan. No Drugs!—No Strenuous Exercise! . . . without starving yourself . . . positively contains no harmful reducing drugs."

Another fraud order was issued against the Vita-Slym Company, which firm, under a variety of names, including V-Tabs Company, promoted vitamin tablets called "V-Tabs." Some of the advertising for these tablets indicated: "By the V-Tab method you need not go on a starvation diet, take habit-forming cathartics or do tiring exercises. Simply reduce the intake of fat-producing elements with the help of V-Tabs which not only reduce your appetite so that you don't want to eat excessively, but also take the place of many fat-producing foods by fortifying your diet with needed minerals and vitamins."

FROM CURRENT KYRON ADVERTISING

CHICAGO MOTHER REDUCES 35 POUNDS IN 7 WEEKS. That's the report of Mrs. Kathryn Walker, 3332 Potomac Ave., Chicago. Photo at right is Mrs. Walker as she looks today. Photo at left is artist's conception of Mrs. Walker when she was overweight.

Artists do imagine, don't they?

In another fraud order, dated Jan. 21, 1947, the Post Office Department denied use of the mails to the A. B. C. Plan Company. This firm advertised: "How would you like to lose 5, 10, or even 20 pounds of ugly fat in a short time? How would you like a slimmer, more graceful, alluring figure without giving up the things you like to eat? Without strenuous exercise, without dangerous drugs?"

In August 1947 another fraud order was issued by the Postmaster General against the Beverly Hills Medical Laboratory and its officers as such at Beverly Hills, Calif. This firm had the "Formula 17 Plan." It was advertised, complete with a picture of a shapely young lady, as "Prominent Beverly Hills Physician Reveals Time-Tested Reducing Plan! Reducing Secrets of Hollywood Movie Actresses. The same successful plan that has cost Hollywood celebrities hundreds of dollars is now brought to you at low cost by their prominent Beverly Hills Physician. It is easy to take off those extra pounds. No harmful drugs or strict diet to leave you craving for food . . ."

The reports of the proceedings leading to these fraud orders show the similarity between these plans and those on the market now, such as "R.D.X.," "Ayds," "Kyron" and "Meltoway." These products are merely the tangible materials in psychologic schemes to obtain the money of the overweight woman.

Medical Economics

THE ISSUE OF COMPULSORY HEALTH INSURANCE¹

A Review by Frank G. Dickinson, Ph.D., Director,
Bureau of Medical Economic Research

When a physician with wide experience in health matters and an eminent student of governmental administration undertake, under the auspices of an outstanding research organization, the task of advising a committee of the United States Senate on two proposals for medical care of the people, an important contribution to medical economics can be expected. This is what George W. Bachman, M.D., Lewis Meriam, Ph.D. and the Brookings Institution have accomplished in a large measure.

In May 1947 the Brookings Institution undertook a study of compulsory health insurance at the request of Senator H. A. Smith, chairman of the subcommittee on health of the Senate Committee on Labor and Public Welfare. Two major proposals for national participation in the provision of individual medical care were before the committee. The first of these proposed federal grants-in-aid to the states to assure adequate medical care for the indigent and medically indigent. The second proposal was for the establishment of a compulsory health insurance system by the national government, with federal regulation and control of the providers of medical services. The Brookings report includes a study of the economic, social and administrative issues involved in the plans; an examination, appraisal and analysis of statistical data bearing on those issues; a discussion of questions which cannot be answered precisely by factual evidence, and a set of conclusions and recommendations given the Committee.

The first major issue considered in the report is the health of the American people. Evidence from prewar mortality statistics discloses a substantial reduction in the past forty years in death rates from typhoid, diphtheria, tuberculosis, infant diseases and childbirth. These reductions are attributed to a combination of medical care, public health work and popular education and "do not suggest basic defects in the American system." International and interstate comparisons lead to the conclusion that, although forty years ago the United States was far behind the world leaders, the health of its white population is now probably better than that of any other great nation. The few countries with generally lower mortality rates are equalled by several of our states with larger populations. Mortality figures also show that nonwhites in the United States have materially poorer health than the whites, but the evidence indicates that this is due more to economic, social and cultural conditions than to inadequate medical care. Despite the claims of critics of the American system of medical care, selective service data do not contradict the conclusions drawn from mortality records. A critical analysis of draft statistics in the report shows them to be unreliable as a measure of national health or of the medical needs of the country.

Statistics on illness and medical care are taken from the survey by the Committee on the Costs of Medical Care in 1928 to 1931 and the National Health Survey of 1935-1936. Both studies locate the chief difficulty in the provision of medical care among the low income groups and, within these groups, among children under 15 and aged persons. Although they permitted wide differences in interpretation, the surveys "did not, however, seem to disclose large volumes of serious illnesses that did not receive medical care." An examination of income and expenditure figures for 1941 reveals that for all classes with incomes above \$1,000, expenditures for automobiles exceeded those for medical care. From such data the Institution concludes that the large majority of American families have capacity to pay for adequate medical care if they are willing to give it a priority above that for certain nonessential or luxury items. Moreover, many of those now unable to pay

for adequate medical care would have to be provided for by philanthropic or public funds under compulsory health insurance because they would be unable to pay the required premiums.

The Brookings report recognizes the limitations of county physician-population and hospital bed-population ratios as indexes of the adequacy of medical service in rural areas. Residents of areas with low ratios may receive medical care from physicians and hospitals in neighboring counties. An attempt now being made to define "medical service areas" and "medical service centers" similar to the trading areas and centers used for commercial purposes promises a clearer picture of the medical care services actually available to the population of a given area.

With reference to the over-all supply of physicians, the report considers it probably sufficient to meet present consumer demand but inadequate to meet all the medical needs of the American people. The report estimates a shortage of about 50,000 dentists at the present time and predicts that the nursing shortage may be as great as 130,000 by 1950. Basing estimates on standards for bed occupancy and capacity set by hospital authorities, some 207,539 additional beds are needed for general and mental hospitals and tuberculosis sanatoriums. Adding the 25 per cent of the 1,468,714 beds now available which are considered obsolete by the United States Public Health Service, a total of 559,128 additional beds would be necessary to meet the hospitalization needs of the American people. These figures lead to the conclusion that the adoption of compulsory health insurance would not immediately make adequate medical care available to all, because the supply of trained personnel and facilities would be insufficient to meet the demand.

Although the Brookings study makes no original estimate of the costs of compulsory health insurance, it cites several factors which would tend to increase medical care expenditures. Insured persons could be expected to make unnecessary demands on the medical care services; some practitioners and agencies would attempt to use the system for their own financial advantage, and administrative expenses would be heavy. If payment is on a fee for service basis, thousands of government employees would be needed to check, audit and investigate claims. If a per capita method is used, the government must allocate each insured person to a general practitioner and must investigate complaints by patients, with perhaps a hearing, decision, penalty and enforcement. A salary system would involve all the problems of government personnel administration, including appointment and promotion, fixing of salary, hours and leaves and disciplinary action.

Experienced members of the Brookings Institution staff have considered the administrative aspects of compulsory health insurance and its effect on practitioners and on the quality of medical service. The conclusions drawn from discussions of these questions are that compulsory health insurance would necessitate a high degree of governmental regulation and control over personnel and agencies providing medical care; that it is improbable that politics could be eliminated from medical care supplied under a governmental system; that the injection of the government into the relationship between practitioner and patient might impair the quality of medical care and that difficulties in the administration of a fee for service system would probably result in the adoption of the more highly socialized per capita or salary system. "It seems questionable whether a country which once embarks on compulsory insurance can turn back but must attempt to remedy defects by more complete government control and administration."

The recommendations in the Brookings report are reminiscent of the majority opinion of the Committee on the Costs of Medical Care. In the judgment of the Institution it would be wise to leave to the individual states the question of compulsory health insurance and to permit each community to make its own arrangements for the provision of medical care. Experimentation would probably lead to a diversity of plans in different sections; if a single pattern were to develop it could then be adopted on a national basis. The Institution recommends that at present the national and state governments might well confine their activities to (a) research and developments in the field of public health, (b) health education at the school level, (c) teaching of preventive medicine, (d) assisting

1. Bachman, G. W., and Meriam, Lewis: *The Issue of Compulsory Health Insurance*, Washington, D. C., the Brookings Institution, 1948, pp. 271.

in the acquisition of facilities and the training of personnel and (c) providing care for the indigent and medically indigent. Adult educational campaigns should be left to voluntary organizations which have enlisted the cooperation of leading laymen. "It must be remembered that good health is not exclusively a matter of medical care; it also impinges upon causative factors that are nonmedical, such as food, shelter, vice and crime, transportation, and industry. Its maintenance depends also upon the intelligence, interest, and co-operation of individuals, families and local communities."

In order that the Brookings report might be of use to the Senate Committee, it had to be prepared in less than a year. Had time permitted, the Institution might have been able better to organize its material and to include more recent statistical data. However, the progressive trend in American medical care is clear; current data would undoubtedly reinforce the conclusions drawn from the study. The discussions of questions not subject to objective answers are well thought out, especially those relating to the administrative problems involved in compulsory health insurance. Insight into such problems gained in previous studies of government and its administration has enabled the Institution and its staff to foresee many of the pitfalls conveniently overlooked by proponents of compulsory health insurance. Certainly the Brookings report throws considerably more light on the practical issues of compulsory health insurance than do the polemic or idealistic contentions of its supporters.

The organization and some of the material reveal haste in preparation. This was forced on the authors, as the book was printed less than twelve months after the request to write it was made in May 1947. Considering the short time available, the volume is well organized and the materials are well selected. The data on medical economics are abundant, but the quality of much of the data is inferior. The authors could have been more discriminating in their appraisal of data on family expenditures for medical care (pp. 181-190). It has been proved that these expenditures are higher percentages of the budgets of the low income family (excluding from consideration both extremes in family income distributions). It has been demonstrated that from birth to death medical needs are described by a U-shaped curve. For males this curve descends rapidly from infancy through adolescence and middle age and rises rapidly later after about age 60. For females the curve is about the same except that it rises during the child-bearing period and is generally higher between infancy and old age. The authors fail to recognize that the age and sex distribution must be the same in all families in each income class in any sample before one can conclude that, within limits, medical care expenditures are not a constant percentage of family income. These U-shaped curves for both sexes strongly suggest that young parents with young children experience the maximum medical needs.

The young fathers in their twenties or thirties have not reached their maximum earning years, for that also follows a curve—an age-earnings progression. The maximum portion of the family budget spent for medical care as the family passes through time is likely to occur when the medical care demand curves are high and when the breadwinner is still on his way up the age-earnings curve. Hence data on portions of family budgets spent for medical care seem to prove that high income families are favored. The authors, who were otherwise discriminating in their use of data, failed to note that such figures may merely show that the peak years of medical expense coincide with the years of low earnings for the young family. The business cycle behavior of medical care expenditures suggests that medical care is both a necessity and a luxury; apparently some of the expenditures for medical care are of the luxury type. These data and a considerable portion of the other standard data used by the authors require extreme caution for proper interpretation.

The contribution of this volume is somewhat greater on the side of administration than on the side of analysis of statistical information. Nowhere has there been a clearer insight into the administrative difficulties with which a program of federal compulsory sickness insurance would be fraught. The relationship of physician to patient would confront governmental

agencies with administrative problems of a different order from those created by any previous exercise of the police power of government. Your reviewer believes that the authors' analysis of administrative problems posed by the two proposals which they were commissioned to examine constitutes their lasting and great contribution to the literature of medical economics.

THE HEALTH OF LOW-INCOME FARM FAMILIES IN SOUTHEAST MISSOURI¹

In 1941 a study of the health of the farm families in Southeast Missouri was made by physicians and dentists under the direction of the medical advisor of the Farm Security Administration. Only those who borrowed funds from the Farm Security Administration were examined. This group included 4,124 persons. Among them, males and females were divided almost evenly, while Negroes represented one third of the group.

The physicians and the dentists found a total of 14,700 defects and diseases among all persons examined, which is an average of 3.8 defects per person. Only 5 per cent were without detectable defects. The most common type of disease was that of the respiratory system, causing one third of the defects. Diseases of the genitourinary system accounted for one sixth of the defects diagnosed, and the diseases of nutrition and endocrine glands also caused one sixth of the defects. There was much need for dental care, and one half of the population needed fillings in their teeth.

Considering the age of the population examined, the older persons had more diseases than the young, and the majority of the population were young since they married at an early age and the birth rate was high. The average number of defects increased from 1.5 for children under 5 years of age to 6.3 for persons 45 years and over. Diseases of the older group include diseases of the circulatory, digestive and nervous systems, while the diseases of the younger group mainly involved tonsils and adenoids.

Women had a larger number of defects than the men, especially in the case of diseases of the genitourinary system. This was also true for diseases of the circulatory system. The most predominant diseases in men were those of the digestive system.

Negroes were reported with about the same number of cases as white persons except when the families were considered as a whole. When this was the case, they exceeded the white persons mainly because the Negro families consisted of more children. The most prevalent diseases among the Negroes were those of nutrition and the endocrine glands. Anemia was twice as frequent in Negroes as it was in white persons.

After the study was completed, the physicians and dentists made recommendations as to the care that should be given. There were 8,595 recommendations made in all, which gave an average of about 2 for each person. Only one tenth did not require recommendation, and this fraction consisted mainly of children. Dental care was the major recommendation, 34 per cent, and next in line was the recommendation for surgical treatment, 24 per cent. Dental care included cleaning of teeth, teeth extractions and fillings. About 95 per cent of the operations necessary were appendectomies, adenoidectomies and circumcisions. The eyesight of these people was not too poor, and only 6 per cent of the recommendations were made for these corrections. At least 1 member in every family, except 1, needed some medical attention. There were 843 families, and there were about 4 or more recommendations made for 95 per cent of the families.

These farm laborers and renters are in the low income bracket and as a result spend little money for their health. Some are medically indigent, although the authors present no analysis of family expenditures. Even if these people could and would spend the money, the facilities available are not adequate to meet all the needs for the group in this territory. The authors stress need, not demand, for medical care; demand

1. The Health of Low-Income Farm Families in Southeast Missouri. University of Missouri, College of Agriculture, Agricultural Experiment Station, E. A. Trowbridge, Director. August 1947, Research Bulletin 410.

comprises desire plus the willingness and ability to pay. These results indicate that better health facilities are required for these people as well as other groups in the same circumstances if all the needs are to be met. Increased facilities could not, of course, provide more medical care unless demand increased. The authors considered the question of financing the program outside the scope of their study.

[Comment: Interesting would be comparison with a similar group in an industrial area. One wonders as to the criteria that determined the need for operations on the appendix that had been delayed or neglected.—Ed.]

Council on Medical Education and Hospitals

GRADUATE TRAINING PROGRAMS ACCEPTABLE BY THE AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY

The Council on Medical Education and Hospitals has limited its approval of programs for graduate training to those offered in connection with general or special hospitals. The following information is published however, at the request of the American Board of Psychiatry and Neurology to indicate the availability of a special type of training which is acceptable to the board and carries full credit toward certification by that board.

Requirements for Acceptance

In order to facilitate the arrangements for training in child psychiatry (which constitutes a major aspect of modern psychiatry), the American Board of Psychiatry and Neurology will accept one year of training in psychiatric clinics for children which may or may not be a part of a hospital approved for residency training, provided such a clinic gives adequate supervision and instruction for full time training during the entire third year of the required three year formal training period. For the purpose of evaluating such clinics, the following conditions and criteria are deemed essential by the American Board of Psychiatry and Neurology:

1. That the clinic have a full time medical director, psychologist, and social worker qualified by training and experience in child psychiatry and allied fields to supervise the training of residents.
2. That the major portion of such training be devoted to therapy adequately supervised by this qualified staff.
3. That the service and teaching activities of the clinic be integrated with those of the community and its social agencies.
4. That clinic work be supplemented by seminars, case conferences, journal clubs or other opportunities for the discussion of the basic principles involved in outpatient work with children and parents, teacher, public health and welfare agency personnel.
5. That such a training clinic be well established in the community with a qualified staff that has operated together long enough as a team to insure stable and sound functioning.
6. That the senior members of the clinic team show evidence of previous experience in the teaching of psychiatry in general, child psychiatry in particular, and their allied fields.

These criteria set forth by the Board pertain more particularly to community-sponsored clinics offering full time training in child psychiatry during the third year of formal residency training. If these clinics are affiliated with hospitals already maintaining approved programs, separate approval is not required unless warranted on the basis of their meeting all requirements for straight fellowship training in child psychiatry.

The following clinics are acceptable to the American Board of Psychiatry and Neurology as qualifying under these provisions.

Center	Director
Children's Psychiatric Division, Langley Porter Clinic, San Francisco.....	Dr. Stanislaus Szutek
Bureau of Mental Hygiene, 1179 Main St., Hartford, Conn.....	Dr. James M. Cunningham
Louisville Mental Hygiene Clinic and Child Study School, 610 South Floyd Street, Louisville, Ky.....	Dr. Spafford Ackerly
The Guidance Center, 1737 Prytania St., New Orleans.....	Dr. Milton E. Kirkpatrick
The Psychiatric Clinic of the Mental Hygiene Society of Maryland, Baltimore.....	Dr. H. Whitman Newell
Children's Center, 244 Townsend St., Roxbury, Mass.....	Dr. Marian Putnam and Mrs. Beata Rank, co-directors
Judge Baker Guidance Center, 38 Beacon St., Boston.....	Dr. George E. Gardner
Amherst H. Wilder Clinic, 279 Rice St., St. Paul.....	Dr. Hyman S. Lippman
Central Clinic, Cincinnati General Hospital, Cincinnati.....	Dr. Maurice Levine
Child Guidance Clinic, 1711 Fitzwater St., Philadelphia 46.....	Dr. Frederick H. Allen
Pittsburgh Child Guidance Clinic, 3004 Victoria St., Pittsburgh 13.....	Dr. Harry M. Little
Children's Service Center of Wyoming Valley, 335 South Franklin St., Wilkes-Barre, Pa.....	Dr. J. Franklin Robinson

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*, Various Centers, Jan. 21, 1949. Final date for filing application is Oct. 1. *Oral*, Philadelphia, Oct. 10. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*, Chicago, Oct. 6. *Written*, Various Centers, January 1949. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral*, Chicago, Oct. 5-8. New York City, Spring, 1949. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PATHOLOGY: Chicago, Oct. 8-9. Final date for filing application is Oct. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

AMERICAN BOARD OF RADIOLOGY: Nov. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

BOARDS OF MEDICAL EXAMINERS

ALASKA: * *Examination*, Juneau, Sept. 7. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

ARKANSAS: *Eclectic Examination*, Little Rock, Nov. 4. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral*, Los Angeles, Nov. 20-21. *Written*, Sacramento, Oct. 18-21. Sec., Dr. Frederick N. Scatenia, 1020 N Street, Sacramento 14.

COLORADO: * *Endorsement*, Oct. 5. Final date for filing applications is Sept. 18. Sec., Walter W. King, 831 Republic Bldg., Denver 2.

CONNECTICUT: * *Examination*, Hartford, Nov. 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven.

CONNECTICUT: * *Homeopathic*, Nov. 9-10. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA: * *Reciprocity*, Washington, Sept. 13. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

GEORGIA: *Examination*, Atlanta, Oct. 12-13. *Endorsement*, Atlanta, Oct. 14. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

ILLINOIS: Chicago, Oct. 5-7. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

INDIANA: *Examination*, Indianapolis, June 1949. Sec., Board of Medical Registration & Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

KANSAS: Topeka, Dec. 15-16. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

MAINE: Portland, Nov. 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Examination*, Baltimore, Dec. 14-17. *Endorsement*, At the discretion of the Board. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

MINNESOTA: Minneapolis, Oct. 19-21. Sec., Dr. J. F. Daluis, 230 Lowry Medical Arts Bldg., St. Paul 2.

MONTANA: Helena, Oct. 4-6. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEVADA: Carson City, Nov. 1. Sec., Dr. G. H. Ross, Industrial Bldg., Carson City.

NEW HAMPSHIRE: Concord, Sept. 9. Sec., Board of Registration in Medicine, Dr. J. S. Wheeler, Room 107, State House, Concord.

NEW JERSEY: *Examination*, Trenton, Oct. 19-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, Oct. 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

NEW YORK: *Examination*, Various Centers, Sept. 27-30. Sec., Dr. J. L. Lochner, Jr., 23 South Pearl St., Albany 7.

OHIO: *Examination*, Columbus, Dec. *Endorsement*, Columbus, Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OREGON: * *Examination*, Portland, Jan. 1949. *Endorsement*, Oct. 15-16. Final date of filing application is Oct. 1. Exec. Sec., Mr. Howard I. Hohlt, 608 Failing Bldg., Portland.

PENNSYLVANIA: *Examination*, Philadelphia, Jan., 1949. Act. Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

PUERTO RICO: *Examination*, Santurce, Sept. 7-11. Sec., Mr. Luis Cucto Coll, 22 Purada, Box 3717, Santurce.

RHODE ISLAND: * *Examination*, Providence, Oct. 7-8. Chief, Div. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: *Endorsement*, Sept. 6. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA: * Jan. 18-19. Sec., Dr. G. J. Van Heuvelen, Pierre.

TENNESSEE: * Sept. 29-30. Sec., H. W. Qualls, 1635 Exchange Bldg., Memphis.

TEXAS: Fort Worth, Nov. 4-6. Sec.-Treas., Dr. M. H. Crabb, 1305 Amicable Bldg., Waco.

VERMONT: Feb. 1949. Sec., Dr. F. J. Lawless, Richford.

VIRGINIA: *Examination*, Richmond, Dec. 3-4. *Endorsement*, Dec. 2. Sec., Dr. K. D. Graves, 3015 Franklin Road, Roanoke.

WEST VIRGINIA: Charleston, Oct. 4-6. Comm., Public Health Council, Dr. N. H. Dyer, State Dept. of Health, Charleston.

WISCONSIN: * Madison, Jan. 11-13, 1949. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls, Wis.

WYOMING: *Examination*, Cheyenne, Oct. 4. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau. Last week in Aug. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARIZONA: *Examination*, Tucson, Sept. 21. Sec., Mr. Francis A. Roy, Univ. of Arizona, Tucson.

ARKANSAS: *Examination*, Little Rock, Oct. 5. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

COLORADO: *Examination*, Denver, Sept. 15-16. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 3.

CONNECTICUT: *Examination*, Oct. 9. Exec. Asst., Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

DISTRICT OF COLUMBIA: *Examination*, Washington, Oct. 18-19. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.
FLORIDA: *Examination*, Gainesville, Nov. 6. Final date for filing application is Oct. 25. Mr. M. W. Emmel, University of Florida, Gainesville.
IOWA: Des Moines, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.
MICHIGAN: *Examination*, Ann Arbor and Detroit, Oct. 8-9. Sec., Mrs. Eloise Lefebvre, 1510 West Allegan St., Lansing.
MINNESOTA: *Examination*, Oct. 5-6. Sec. Treas., Dr. Raymond N. Brier, 105 Millard Hall, Univ. of Minnesota, Minneapolis.
NEBRASKA: *Examination*, Omaha, Oct. 5-6. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln.
OKLAHOMA: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.
OREGON: *Examination*, Portland, Sept. 4. Sec., Basic Science Examining Committee, Dr. C. D. Byrne, Univ. of Oregon, Eugene.
SOUTH DAKOTA: *Examination*, Vermillion, Dec. 3-4. Sec., Dr. G. M. Evans, Yankton.
TENNESSEE: *Examination*, Memphis & Nashville, Sept. 20-21. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.
WISCONSIN: *Examination*, Madison, Sept. 25. Final date for filing application is Sept. 18. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospital Records as Evidence of Cause of Accident.—The plaintiff sued for damages for injuries alleged to have been caused by the negligence of one of the defendant's bus drivers. After a verdict for the plaintiff the defendant filed a motion for a new trial which was heard in the superior court of Delaware at New Castle.

The plaintiff testified that while he was attempting to board a bus operated by the defendant the door was closed on his ankle and the bus started, throwing him to the ground with a sharp twist to his ankle. There were no witnesses to the accident. The defendant, while not denying the injury, contended that the plaintiff was hurt, not in attempting to board its bus, but because he twisted his ankle while walking at or near the bus stop. In support of this contention, the defendant offered in evidence certain hospital records which contained a statement purportedly made by the plaintiff that he had broken his ankle by twisting it while walking along the sidewalk. The hospital intern who treated the plaintiff for his injuries on the night in question was called to the stand to qualify the hospital report for admission under the Uniform Business Records Act.

The plaintiff's counsel objected to the admission of that part of the hospital record containing the words "Patient states he twisted ankle while walking along street" for the reason, among others, that such language did not constitute an entry made in the regular course of the business of a hospital.

The court pointed out that in theory regular entries constituting the business records of a corporation or institution, and otherwise conforming to the safeguards set out in the act, are said to be so stamped with the reasonable guarantee of trustworthiness as to justify their admission in evidence as an exception to the hearsay rule. The court then proceeded to discuss a number of cases discussing the applicability of this doctrine to hospital records and said that these opinions disclosed near uniformity of judicial thought in at least two respects: (a) all matter contained in a business record is not admissible *per se* merely because regularly entered in accordance with some preconceived policy established for the conduct of a particular business and (b) to be admissible, the subject matter of the entry must be within the scope, or course, of the business, though some courts are more liberal than others in defining what the scope of a particular business may be. Thus, the mere fact that the statement in this case was regularly entered on a standard hospital form under the heading "state where and how this accident happened" would not of itself render admissible all matter entered thereunder. The rule running through the cited cases seems clearly to be this, said the court, that admissions by patients against their interests, regularly entered in hospital records, may be received in evidence at a trial only if so related to the complaint or injury involved as to facilitate prompt and intelligent diagnosis and treatment. The plaintiff's statement to the effect that he twisted his ankle while walking along the street was, said the court, "pathologically germane" to the injury which necessitated his attendance at the hospital. It is reasonable to suppose that the words "while walking along the street" were not merely descriptive of the injury and thus altogether irrelevant, but aided the attending physician to some extent in diagnosing and treating the fracture. The knowledge that the injury had occurred from a twist while walking ruled out the possibility of the ankle having been crushed. The physician testified that it was necessary for him to know how the injury occurred in order properly to treat it. In the instant case this seems particularly true because at the time of the plaintiff's admission to the hospital a roentgenologist was not available. Immediate treatment of the injury therefore had to be given without benefit of roentgenogram, and the statement as to how the accident happened was of more than usual importance. Hence the court concluded that the statement was properly recorded within the scope of hospital business. Accordingly the new trial requested by the defendant was granted.—*Watts v. Delaware Coach Co.*, 58 A. (2d) 689 (Del., 1948).

Medical Motion Pictures

FILM REVIEWS

The Physiology of Normal Menstruation. 16 mm., color, sound or silent, 810 feet (1 reel), showing time twenty three minutes (sound speed). Prepared in 1948 by Somers Sturgis, M.D., Associate Surgeon, Massachusetts General Hospital, Boston, and John Rock, M.D., Free Hospital for Women, Brookline, Mass. Produced by Sturgis-Grant Productions and sponsored by Schering Corp., Bloomfield, N. J. Procurable on loan from Medical Service Department, Schering Corporation, Bloomfield, N. J.

This film explains the physiology of normal menstruation clearly and concisely. It so describes the relation of the five principal hormones involved in the menstrual process that the listener can absorb and retain the information.

An introductory statement of what is to be discussed in the film is followed by animated drawings explaining the effect of the three anterior pituitary hormones—namely, the follicle-stimulating hormone, the luteinizing hormone and luteotropin—on the ovary. The entire relationship and the effect on the uterus of the two ovarian hormones, estrogen and progesterone, are reviewed.

The presentation plus the reviews enables one to fill in the gaps in his understanding of the rather confusing interplay of the hormones. The relationships of these hormones are not completely clear to experts in this field. To the average physician they are frequently confusing. This film should be informative to the majority of practicing physicians, medical students and the nursing profession. It could also be used as the basis of an advanced lecture on the more detailed hormonal ramifications of menstrual physiology, or in a similar manner as the basis for discussion of the clinical aspects of menstrual disorders. The authors have combined the art of teaching and the art of visual education very well.

NEW MOTION PICTURE ADDED TO THE A. M. A. LIBRARY

The Story of Menstruation. 16 mm., color, sound, 400 feet, showing time ten minutes. Now available on a loan basis through the Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

This film in colored animation and accompanied by carefully worded commentary begins by indicating the manner in which the pituitary gland governs first the growth of the body and later the function of the ovaries. Next it shows ovulation and the passage of the unfertilized ovum. The thickening and the subsequent menstrual shedding of the endometrium are shown, followed by suggestions as to bathing, diet, exercise and other hygienic measures in relation to menstruation.

The production is intended for showing to groups of adolescent girls in the 14 to 18 year age range to explain the physiology of menstruation with some practical corollaries.

Physicians called upon to address lay audiences such as Girls' School, Parent-Teachers' Association, Women's Club, etc., may find this film a useful adjunct to their lectures.

(A review of "The Story of Menstruation" was published in THE JOURNAL, 133:1033 [April 5] 1947.)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

American Journal of Clinical Pathology, Baltimore

18:273-348 (April) 1948

- Pathology of Hypersplenism. E. von Haam and A. J. Awany.—p. 313.

Lipotropic Therapy in Fatty Metamorphosis of Liver.—The 15 patients selected for this study by Franklin and his associates had enlarged livers with moderate to severe fatty infiltration as proved by initial needle biopsy. Group I consisted of 5 persons without cirrhosis, the severe fatty changes in the liver being presumably due to disturbed nutrition. Group II consisted of 10 patients with fatty cirrhosis. Most of these presented some of the usual signs and symptoms of cirrhosis such as ascites, jaundice, splenomegaly, spider nevi and gastrointestinal disturbance, as well as laboratory findings of impaired hepatic function. Different types of lipotropic therapy were employed; namely, cystine plus choline, methionine and diet high in protein and in vitamin B complex. Clinical improvement, as evidenced by subjective and objective findings, was noted in almost all patients after "lipotropic" therapy. Functional improvement was evident by all tests performed except the thymol turbidity and total cholesterol tests, results of which remained abnormal. Disappearance of fat and regeneration of parenchymal cells were noted in all instances. Observations on these patients support the efficacy of lipotropic therapy in the removal of fat from human fatty cirrhotic and noncirrhotic livers. This was found associated with clinical and functional improvement. No evidence was found that with the removal of fat the cirrhotic process is arrested.

Papanicolaou's Method of Cancer Diagnosis.—Wiles and Helliwig report on Papanicolaou's method practiced in more than 100 cases on the gynecologic service of a hospital and a tumor clinic in Wichita, Kan. The method has been used with an average accuracy of 80 per cent. Papanicolaou's method has a definite, but limited, usefulness wherever biopsy or curettage is not feasible. Where a suspicious lesion is accessible to biopsy or curettage the vaginal smear method is not indicated. The vaginal smear does not permit differentiation between changes due to irradiation, carcinoma in situ and invasive carcinoma. Tissue examination cannot be replaced by vaginal smears in the definite diagnosis of cancer. The high percentage of false negative smears in endometrial carcinoma counts heavily against the use of vaginal smears as a screening test in cancer detection clinics.

Effects of Shock on Kidney.—Van Slyke discusses shock caused by hemorrhage, burns, trauma, dehydration or other injury in which there is an inadequate volume of blood to fill the vascular bed. Prostration, cold perspiration and bloodless or cyanotic skin are the visible effects. An immediate effect of shock is a decrease in renal blood flow and function, which may lead to complete anuria. Compensatory constriction of nonrenal peripheral vessels follows, and if the loss of circulating blood volume has not been too severe, renal blood flow and function may be quickly restored. If shock is severe, the kidney is included in the peripheral constriction. Renal constriction and anuria in this phase may continue even when the arterial blood pressure is as high as 100 mm. If renal ischemia does not continue too long restoration of renal function quickly follows restoration of the general circulation. If severe renal ischemia continues for a sufficient number of hours, the second, or renal damage phase, of renal shock develops. The most obvious visible damage is located in the cells of the loop of Henle and the distal tubules. Tubular reabsorption of excretory products from glomerular filtrate appears to be the most probable cause of renal failure in this phase. If the renal damage is not too severe gradual recovery of the kidneys may occur. In fatal cases anuria or inadequate excretion persists, and death in uremia occurs in two to twenty days. To diminish the danger of death from postshock uremia it is advisable to cut the duration of shock as short as possible by quick restoration of blood volume. If acidosis is present, sodium bicarbonate should be administered. While administration of large amounts of fluid may be necessary to obtain normal blood volume and hydration, overadministration is to be avoided. Measuring blood and plasma specific gravities assists in guiding administration of

fluid. When, after recovery from acute shock, anuria or excretion of urine of low volume and specific gravity persists and blood urea continues to mount, a diet high in carbohydrates and fat and low in protein should be given to retard accumulation of catabolic products. Vividiffusion or peritoneal irrigation may retard onset of uremia and increase the opportunity for recovery of renal function.

Splanchnic Resection in Malignant Hypertension.—Peet and Isberg stress that once the diagnosis of malignant hypertension has been made arrangements should be made for treatment by splanchnic resection, because timely surgical treatment offers sure hope to the victim of this terrible malady. During the time from November 1933 to December 1941 a total of 162 cases were diagnosed as malignant hypertension and were surgically treated. Follow-up information was inadequate in 19 cases. This is a study of 143 patients followed for five to twelve years after surgical treatment. Diastolic blood pressure levels varied between 140 and 190 mm. Headache, visual disturbance and dyspnea were the most common complaints. Ninety-one per cent of the patients had organic heart disease; 84 per cent had impaired renal function and 20 per cent had experienced cerebrovascular accidents. The operative mortality in malignant hypertension was 10 per cent. The five year survival rate in the 143 cases was 21.6 per cent. All living patients receiving a fundoscopic examination five years and more after operation showed no evidence of papilledema. Four patients were maintaining blood pressure levels within normal range five to eleven years after operation. If splanchnic resection can be performed early, before heart disease has occurred, the outlook is good, for 11 of 13 such patients with malignant hypertension were living five to twelve years after operation. Once renal function becomes moderately or markedly impaired, splanchnic resection is futile.

Distribution of Poliomyelitis Virus After Epidemic.

Francis and Brown say that in the summer and fall of 1945 Tennessee experienced an epidemic of poliomyelitis which involved principally rural areas. Since the date set for the opening of schools followed shortly on a heavy incidence of poliomyelitis, an opportunity was presented to obtain information relative to the presence of infection in the pupils arriving from the farms on opening day and to study the possible spread of virus, as measured by its detection in the stools of children in the school. Two rural schools, with 48 and 51 pupils respectively, were selected for study. In one school none of the pupils had detectable virus in his intestinal tract at the time of the first collection, but virus was isolated from 1 person two weeks later. It appears probable that this person had acquired the infection outside the school, as all pupils were free from the virus at the time of the original collection; in this instance there was a history of earlier association with a paralytic case of poliomyelitis. In another school, 2 children were carrying virus on the opening day but only 1 of these still carried it two weeks later, and no other children in the school acquired the infection. Thus the study yielded no evidence of significant dissemination of virus in the groups. The results indicate again the relative differences in efficiency between close familial association and the less intimate nonfamilial contact in the transmission of poliomyelitis virus.

Roentgenography of Gastrointestinal Tract Following Resection of Vagus.—Ritvo and Shauffer made roentgenographic studies on 29 patients with transthoracic section of the vagus nerve and 4 with transabdominal resection of the vagus nerve. In the early postoperative stages there was definite gastric dilatation and atonicity in most cases. Sluggish, ineffective and arrhythmic peristalsis or absent peristalsis was associated with dilatation and atonicity. Emptying times, both initial and final, were increased. These changes occurred to a lesser degree in patients with previous gastroenterostomies and in those with partial gastrectomies. Two patients had gastroenterostomies after vagotomy for dilatation and retention. Follow-up studies showed a return toward the normal from these changes within six months to a year. Complete return to normal in all respects was not found in any case. The ulcers healed promptly after operation. This was especially striking in the cases of stomal and jejunal ulcers in the patients with partial gastrectomy. The postoperative size of the small bowel was not remarkable in any case; the motility was slow, apparently owing to the delay in emptying of the stomach. In 1 patient temporary dysphagia developed after transabdominal resection of the vagus nerve.

Clinical Experience with Nitrogen Mustard.—Faloan and Gorham report on the use of methyl-bis (beta-chlorethyl) amine hydrochloride in 15 patients. All patients except 1 received intravenous injections on four consecutive days of 0.1 mg. of methyl-bis (beta-chloroethyl) amine hydrochloride per kilogram of body weight. The injection was made intravenously through the tubing of rapidly flowing isotonic solution of sodium chloride. The procedure is carried out within five minutes after dissolving the nitrogen mustard. All patients were followed with complete blood counts at least twice weekly for the three weeks following injection. The use of nitrogen mustards in Hodgkin's disease, polycythemia vera and lymphosarcoma will frequently induce temporary remissions. Experience, confirming that of other workers, does not allow a similar view of the leukemias treated with this substance. The toxic effects of the drugs make them potentially dangerous, and they must be used with care, both in handling and in the follow-up of their effects on the hematologic picture.

Ringworm of Scalp.—Montgomery says that from 1940 to 1947, inclusive, 2,857 cases of tinea capitis have been studied at the New York Skin and Cancer Unit. Of these, 83.3 per cent were caused by *Microsporon audouini*. There has been a sharp increase in ringworm of the scalp since 1943, and a substantial relative increase of infection with *M. audouini*. Three cases of infection with *Trichophyton crateriforme*, 4 cases of infection of the scalp with *Trichophyton sulfureum* and 4 cases of infection of the eyelashes with *M. audouini* are reported.

Sympathectomy in Hypertension.—Findley maintains that sympathectomy for hypertension has not been placed on a rational basis. The one known basic fact is that elevation of blood pressure is due to increased peripheral resistance, but there is as yet no agreement as to whether the arteriolar constriction is of humoral or nervous origin. Constitution, arteriosclerosis, renal function, nervous system, endocrine organs and pregnancy are some of the factors that may exert vasoconstrictor influences. Any enlargement of the vascular bed which follows sympathectomy is probably temporary. In the author's experience with about 100 hypertensive patients who have been subjected to a bilateral splanchnicectomy and excision of both sympathetic chains from the fourth or fifth thoracic through the second lumbar ganglions, nothing resembling a "cure" was ever seen. Invariably, the blood pressure slowly rises after the operation to or somewhat below the preoperative level. Patients should not be selected for operation solely on the basis of tests which measure only fluctuations in blood pressure. Procedures such as the cold pressor test, the "amylal" sedation test, splanchnic block and the induction of high spinal anesthesia have proved notoriously unreliable. The operation should be reserved for patients with severe symptoms but no gross impairment of cerebral, cardiac or renal function. The operation should not be done on young persons with mild asymptomatic hypertension. Sympathectomy may profitably be done on patients over 50 years of age, provided that other requirements are met. Patients should be told that sympathectomy offers palliation and not cure.

Para-Aminobenzoic Acid in Rheumatic Fever.—Belisle treated 3 patients, 2 men aged 30 and 54 respectively and a woman aged 21, who had rheumatic fever with sodium salicylate combined with para-aminobenzoic acid. Twenty-four grams of para-aminobenzoic acid was given by mouth daily in fractional doses of 2 Gm. every two hours. By this combined treatment the initial level of the sodium salicylate in the blood was increased two to five times. Thus a therapeutic concentration of the salicylate in the blood recommended by majority of the authors—i. e., 35 mg. per hundred cubic centimeters—was obtained, and in some instances with relatively small doses of sodium salicylate. There was a drop in the salicylate level in the blood of these patients when the administration of para-aminobenzoic acid was discontinued. The para-aminobenzoic acid will have its place in the therapeutic armamentarium for rheumatic fever, particularly in those instances in which an optimum therapeutic concentration cannot be obtained by administration of the sodium salicylate alone. The clinical employment of the para-aminobenzoic acid may be limited by its obligatory administration every two hours.

Surgery of Intervertebral Disk Protrusion.—Falconer and his associates are concerned with factors which make for success or failure in intervertebral disk surgery, particularly as applied to the lumbar region. The study is based on an analysis of the clinical, operative and follow-up observations in 100 consecutive patients subjected to operation with their condition diagnosed as prolapsed lumbar intervertebral disk. A careful selection of cases is the most essential. All patients suffering from severe sciatica and/or pain low in the back should be treated first by rest in bed or immobilization for at least one month. Patients whose sciatica is not relieved appreciably by rest in bed should then be carefully investigated. A few will prove to have lesions like cauda equina tumor or granulomatous or neoplastic disease of the spine, but most will have disk lesions and should have surgical operation. The affected intervertebral disk must be exposed adequately. If this should prove difficult to achieve by an interlaminar approach, a laminectomy should be performed, for a poor exposure prevents the surgeon from curetting thoroughly the interior of the disk. Provided the interarticular joints are left intact, a laminectomy does not permanently weaken the spine. Disk prolapses may be divided into four groups, projections, extrusions, intermittent prolapses and scarred disks. Intermittent prolapses in particular, are a group which are apt to be overlooked at operation, and it is probable that many of the negative explorations occurred in cases involving this type of lesion. In order to avoid persistence or recurrence of symptoms, it is essential to remove all loose and readily detachable tissue from within the pathologic disk. In many instances this necessitates exposure and curettage of the pathologic disk from both sides of the theca. During convalescence the patient should undergo graduated exercises and physical training designed to strengthen weakened erector spinae muscles and to promote general physical fitness. This hastens the return to work. Spinal fusion is seldom warranted. If, after operation for disk prolapse, symptoms persist or recur, reexploration should be considered. Continued symptoms have often been due to an inadequate removal of the diseased disk.

Posterior Gastroenterostomy for Pyloric Stenosis.—Reid and Marcus review the results of gastroenterostomy in 80 cases of pyloric stenosis. The operations were performed by different surgeons at the Liverpool Royal Infirmary between 1928 and 1938. Organic pyloric stenosis commonly is the result of a long standing duodenal ulcer which in the process of healing occludes the pylorus, with resulting gastric hypertrophy and dilatation. The scarring may be so great that the pylorus only admits a bristle. The patient is subjected to slow starvation and dehydration. Copious vomiting occurs in the majority of cases. In all cases under review patients were treated by a posterior no-loop vertical isoperistaltic gastroenterostomy with a large stoma. The average age of the patients at the time of operation was 50 years. Two of the patients died as the result of the operation and 15 others could not be traced for follow-up. Of the 63 who could be traced, 9 died within ten years; the

other 54 were alive over ten years after the operation. The general impression is gained that gastroenterostomy is definitely worth while. Most of these patients expressed their gratitude for the operation and believed that it had benefited them. The average period of convalescence after operation is four weeks. In partial gastrectomy it is much longer. The diet was a normal mixed diet. Anemia and vitamin deficiency did not occur. There was no evidence of the so-called dumping syndrome, which occurs in a considerable percentage of the patients after subtotal gastrectomy. The authors believe that with modern anesthesia, chemotherapy, and adequate preoperative and postoperative measures, the operative mortality should not be more than 1 per cent.

Sympathectomy of Upper Limb.—The fifty-six limbs studied by Barcroft and Hamilton were those of persons who had undergone sympathectomy for Raynaud's disease, Raynaud's phenomenon, thromboangiitis obliterans, causalgia and trophic ulcer. The interval between operations and investigation varied from a month to six years. All the sympathectomies were preganglionic sections. Examinations of seventeen upper limbs from one to six months after sympathectomy, in the form of a preganglionic section, revealed no recurrence of attacks in fourteen of sixteen hands operated on for Raynaud's phenomenon; in two hands the attacks were less frequent and less severe. Vasomotor and sudomotor reflexes were absent. This indicates that preganglionic section completely sympathectomizes the limb; there is no outflow to the hand above the second thoracic anterior spinal nerve root. Examination of the other thirty-nine upper limbs from one to six years after preganglionic section showed considerable clinical improvement. There was no recurrence of vasospastic attacks in eighteen of thirty-six limbs operated on for Raynaud's phenomenon. In fourteen hands the attacks were less distressing; only 4 patients had obtained no benefit. Vasomotor and sudomotor reflexes, though absent in some limbs, were present in many. It follows that a nervous connection between the brain and the vessels and sweat glands of the hands is often reestablished. The persistence of the excellent clinical results, in spite of the reestablishment of a vasomotor path, probably signifies that the new path is functionally inferior to the original. Partial regeneration is the most likely explanation of the new nerve path.

Fructose and Fructolysis in Semen.—Mann asserts that the survival of spermatozoa within ejaculated semen depends largely on the supply of nutrient material in the seminal plasma. The nutrient substance present in the seminal plasma is a reducing and glycolyzable carbohydrate. The nature of the glycolyzable carbohydrate remained unknown until recently, when chemical investigations have shown that the seminal sugar is d-fructose. The survival of spermatozoa in ejaculated semen depends largely on the amount of fructose in the seminal plasma. The formation and secretion of fructose in the male accessory sex glands is controlled by testicular hormone. The amount of fructose present in semen can be measured colorimetrically. A method of doing this is described. A low fructose level in the semen suggests either hormonal or spermatozoal deficiency; but a high semen-fructose level does not necessarily indicate spermatozoal efficiency. The level is normally subject to fluctuation. Fructose disappears from semen incubated in vitro; the rate of fructolysis indicates the amount of spermatozoal metabolic activity. Fructolysis plays an essential part in the survival of stored spermatozoa, as used in artificial insemination.

Autotransplantation of Joint Capsule in Rheumatoid Arthritis.—Novotny observed that when patients with rheumatoid arthritis undergo certain operations, they often show signs of possible desensitization. On the presumption that the course of the disease is connected with allergic phenomena, he has tried to produce a state of desensitization by means of a transplantation of the diseased tissue of the capsule, preferably from the patient's knee joint, subcutaneously to the lower umbilical region. In 11 of the 12 cases described, a favorable postoperative reaction appeared, with reduction of pain and swelling and an increase of the mobility of the joints. In 1 case there was not a reaction, and in this case the transplanted tissue became necrotic. Of the 11 patients, 7 have remained in a better condition after operation. The period of observation has been nine months in 1 case and twelve to seventeen months in 6 cases. Two patients had a complete and 2 a partial relapse in the course of a year.

Hemorrhagic Thrombocytosis.—Mortensen reports the case of a man, aged 64, who had had symptoms of polycythemia vera which had later been followed by a leukemia-like condition. There was a hemorrhagic tendency, while the thrombocyte count was 6,000,000. Coagulation time and prothrombin time were normal. There was marked neutrophilic leukocytosis with eosinophilia. There were signs of gastroenteritis as in a number of the cases earlier described. The syndrome is regarded as a malignant hyperfunction of the bone marrow of the same type as myeloid leukemia and polycythemia vera.

*Carcinoma of Gallbladder. J. de Brito.—p. 9.

Carcinoma of Gallbladder.—Carcinoma of the gallbladder is rare. The cirrhotic type is the most frequent. The early symptoms are those of lithiasis. As the disease progresses the tumor becomes palpable, hard and painful. Pain radiates to the ribs of the right side and to the right lung. The late stage is characterized by aggravation of the digestive disorders, anorexia, acute anemia, jaundice, symptoms due to metastases and progressive cachexia. The diagnosis is difficult. The therapy is one of prevention, consisting of a cholecystectomy as soon as the diagnosis of gallstone disease is made. The prognosis is unfavorable.

Encephalogram After Typhus. F. Schmieder.—p. 14.

Circulatory Dynamics and Sympathetic Tonus in Presence of Arteriovenous Fistulas.—Gauer and Linder say that observations during the first world war demonstrated that arteriovenous aneurysms resulting from gunshot injuries of peripheral vessels not only produce circulatory disturbances locally, in the involved part of the body, but also exert an effect on the heart and on the general circulation. Nearly 400 aneurysms were observed during the second world war at the clinic in Heidelberg and 150 arteriovenous fistulas were operated on. During the first year after the war 16 patients with arteriovenous fistulas were studied. Depending on the size of the communicating opening in an arteriovenous opening, the peripheral circulatory resistance is reduced by about 40 per cent or more. In order to maintain an adequate blood pressure, the minute volume of the heart is correspondingly increased. This chronic increase in the performance of the heart leads to cardiac dilatation and insufficiency. Permanently increased performance

of the circulation is accompanied by an increase in venous tonus and changes in the muscle structure of the heart, which is manifested in a dilatation of the cardiac cavities. If the fistula is closed, many hours are required until equilibrium is restored. The circulatory changes caused by the arteriovenous fistula are capable of regression. Early surgical removal of the circulatory short circuit is advisable.

Genesis of Megaloblastic Blood Formation.—Haenel presents observations on bone marrow punctates of patients with pernicious anemia. He concludes that megaloblasts derive from undifferentiated reticulated cells. Megaloblastic blood formation is mesenchymal in contradistinction to normal parenchymatous erythropoiesis. A second factor must be assumed for the development of megaloblasts. This factor is the loss of the heteroplastic divisibility of the cell which is regarded as the morphogenetic manifestation of the lack of the antipernicious anemia principle. The peculiarity of the megaloblastic structure of the nucleus is interpreted as the persistence of mesenchymal characteristics of the nucleus.

Congenital Ectodermal Defects and Oligophrenia. A. Touraine.—p. 1767.

Psychologic Aspects of Oligophrenia. P. Pichot.—p. 1771.

Phenylpyruvic Oligophrenia.—Delay points out that in the group of oligophrenias a distinction should be made between those which depend on exogenic and those which depend on endogenic and genetic causes. The author designates the first as oligophrenites and the second as oligophrenoses. The former are the results of exogenic factors such as trauma and toxic infection, the latter represent degenerative disease. Certain oligophrenoses of recessive monomeric heredity with metabolic disturbances are of special interest from the point of view of general pathology, for instance, amaurotic idiocy of Tay-Sachs, which is accompanied by disturbances in the lipid metabolism, and phenylpyruvic oligophrenia, which is accompanied by metabolic disturbances of proteins and more especially of amino acids.

Phenylpyruvic Oligophrenia.—Delay, Polonovski and other investigators review the clinical genetic and biologic aspects of phenylpyruvic oligophrenia. They give particular attention to reports by Fölling of Norway, who was first to call attention to the presence of phenylpyruvic acid in the urine of patients with oligophrenia and also suggested the probable genetic nature of this disorder. The authors consider, in addition to Fölling's contributions, those of several other observers and cite a case of their own. The new fact they stress is a considerable disturbance detectable in tests of hepatic function. Phenylpyruvic oligophrenia possibly represents the key to a large number of problems in psychiatry, neurology, genetics and biochemistry. The first results obtained in studies on this problem, although they give no definite solution, open an almost unlimited field for new investigations on pathogenic mechanisms that may throw new light on familial disorders of the nervous system and on the relation between biochemical disturbances of genetic origin and psychiatric disturbances; they give an explanation for a process which has been spoken of as degeneration or abirotrophy.

Encephalography in Oligophrenia.—Delay and his co-workers describe the technic used by them and experiences with this method in 70 patients with oligophrenia. The method represents practically an anatomic examination on the living. Certain diagnoses can be verified only by this method, for instance, cases of agenesis of the corpus callosum or the syndrome of Little with median ventricle. Encephalography facilitates differentiation of a syndrome like microcephalia and its different forms. It is also a valuable aid in prognosis. Although the information obtained so far is still fragmentary, the first results are encouraging and suggest that the solution of these problems is found only by comparison of numerous, encephalographic records with information obtained by clinical, genetic, psychologic and biologic studies on patients with oligophrenia.

Book Notices

The Care of Chronic Disease in Pittsburgh and Allegheny County. A Survey. By Claude W. Munger, M.D., and Mary C. Jarrett. Under the Auspices of Federation of Social Agencies of Pittsburgh and Allegheny County Health Division. Loose-Leaf. Paper. Various pagination. Health Division, Federation of Social Agencies, 519 Smithfield St., Pittsburgh, 1917.

A comprehensive and detailed study of the needs of patients suffering from chronic diseases is embodied in the survey prepared for Pittsburgh and Allegheny County. In 1900 persons over 65 years of age constituted 4.1 per cent of the population of the United States, and, in 1940, 6.8 per cent; reliable estimates indicate that by 1960 they will comprise over 9 per cent of the population.

Other studies indicate that 10 per cent of the general population suffer from chronic disease, of whom 1 per cent are incapacitated invalids. Something of the magnitude of the problem is expressed in these figures, and the facilities for the care of such patients have been scant and inadequate. Too frequently it has been the tendency to approach the problem as though it were medically isolated, and patients are given the barest necessities to sustain life. Present sentence in a modern penal institution is frequently far less harsh than life in an institute for the chronically ill, where patients sit in long rows beside their beds or on hard benches in corridors or congregate in crowded basement flooded with the raucous noise from a radio loud speaker. Almost no attempt is made to provide diversional or recreational facilities, and patients of different social and ethnic background, of varied life experiences, are all herded together in the belief that similarity in years is synonymous with unanimity of purpose and outlook in life.

Dr. Munger and Miss Jarrett have offered some excellent suggestions to alleviate the plight of the chronically ill. Voluntary homes for the chronically ill should be expanded in numbers and their facilities increased by the addition of regular medical service given by competent physicians, satisfactory dietary facilities, the services of medical social workers and the development of suitable recreational programs. Many of the techniques long used in hospitals for acutely ill patients should be translated for use in homes for the chronically ill. Nursing homes can become another valuable means of meeting the problem of the chronically ill. A system whereby there is a division of the chronically ill and those requiring hospital services and those requiring home services is essential in the provision of competent medical service. A plan whereby hospitals would be located on or near the campus of the medical schools would attract a better class of physicians and would allow the possibility of using these patients for teaching purposes by the medical school. Resident and undergraduate instruction could also be used if the medical college were asked to nominate the staff physicians.

Boarding as well as apartment houses could be adapted to the use of old age assistance pensioners and would also help meet some of the problems of the chronically ill.

The erection of satisfactory community homes for the chronically ill is of vital concern and requires careful planning by leaders of the medical and social fields. Arrangements by which patients are allowed to pay for their services in accordance with their available resources might well be incorporated in such a plan. Community planning on a large scale would not be as expensive a program as would appear at first sight, since through neglect there are serious loss of earning power, family disintegration and individual suffering not usually recognized. In terms of over-all community gain, it would be cheaper to plan, build and maintain satisfactory facilities for the chronically ill, and rehabilitate a sufficient number of them to make the plan remunerative to a certain degree.

The authors are to be commended on their courage in offering a sound, sensible plan for a seriously neglected phase of medical care. The book is recommended to all physicians and social workers, who must inevitably face the problems of the chronically ill and the aged. It is regretted that the book is mimeographed and that not all pages are easily readable. Another slight defect of the book is that the pagination is by

chapters rather than continuous; also, the lack of an index makes an otherwise excellent book a little difficult as a reference book. In spite of these small blemishes it is an outstanding report on a serious current problem.

Disability Evaluation: Principles of Treatment of Compensable Injuries. By Earl D. McBride, B.S., M.D., F.A.C.S., Assistant Professor in Orthopedic Surgery, University of Oklahoma School of Medicine, Oklahoma City. Fourth edition. Fairbaird. Price, \$12. Pp. 667, with over 400 illustrations. J. B. Lippincott Co., E. Washington Sq. Philadelphia 5, 1918.

This book is made up of numerous detailed tables, accompanied and elaborated by informative reading matter regarding the injuries of industrial occupations. These injuries are discussed from various points of view: subjective and objective symptoms, physical signs, methods of examination, differential diagnoses, treatments and prognoses. But these all lead up to the discussions on the evaluation of disabilities resulting from injuries.

The tables and formulas, which are the core of the work, are extensive and are arranged to give practically foolproof answers—providing that the reader knows how to solve them. A large proportion of readers will find them difficult to use because they are complicated.

In the text as well as in the tables and formulas there is lack of clearness and simplicity of style. There is much valuable and dependable information throughout the book in regard to the workmen's compensation laws as they are enacted in the various states, and this without formidable legal phraseology. The sections on malingering, the tables showing the healing periods required for fractures, and the chapter on "The Industrial Back"—not an apt title—are among the best. An important omission from discussion is Sudek's atrophy (causalgia).

This volume is a somewhat sloppy job of bookmaking, as shown by the haphazard page numbering, obvious errors and inadequate index.

Factors Regulating Blood Pressure. Transactions of the First Conference, April 24-25, 1917, New York, N. Y. Edited by B. W. Zweifach and Ephraim Shorr. Loose-Leaf. Paper. Price, \$1.90. Pp. 175, with 10 illustrations. Josiah Macy, Jr. Foundation, 365 Park Ave., New York 21, [n. d.].

This volume reports the transactions of the First Conference on Factors Regulating Blood Pressure, held under the auspices of the Josiah Macy Jr. Foundation in April 1917. The Macy Foundation and its director, Dr. Frank Fremont-Smith, have done much in recent years to advance biologic and medical science through the sponsoring of meetings of small, informal conference groups of laboratory and clinical investigators in several fields, including that of blood pressure. The first meeting of the conference (presided over by Dr. Harry Goldblatt) was concerned mainly with experimental and human hypertension, but future meetings will include consideration of cardiovascular mechanisms in health and in diseases other than hypertension, as well as renal function and malfunction.

Inclusion of the thirteen formal presentations of the two day conference and the discussion following each renders this volume an excellent summary of the current views of leading American and Canadian investigators in the field of hypertension. The pathogenesis and treatment of experimental hypertension were considered under the following headings: (a) the role of the nervous system in experimental renal hypertension; (b) the concept that experimental renal hypertension is due to renalcretory deficiency; (c) hepatorenal vasotropic factors in experimental renal hypertension; (d) salt choice by renal hypertensive animals; (e) methods of producing and studying experimental hypertension; (f) renin tachyphylaxis and (g) the effect of renal extracts and antirenin in experimental renal hypertension. Human hypertension was discussed as follows: (a) humoral factors in renal blood flow, (b) treatment with low salt and low protein diets, and (c) treatment with renal extracts, tyrosinase and quinones.

The evidence reported at the conference suggests that the pathogenesis of a presently unknown percentage of cases of essential hypertension is on a renal basis and that the renal mechanism involved is not yet determined but may be an increased secretion of renin, an increased formation of pressor amines or a decreased secretion of a hypothetic renal hormone.

Para-aminohippurate clearance and extraction studies gave no support to the possibility that renal arteriovenous shunts are operative and important in the kidney of essential hypertension. Discouraging results with the treatment in essential hypertension by the rice diet and by sympathectomy, quinones and renal extracts were reported. Nevertheless, the conference demonstrated that slow but steady progress is being achieved in the study of hypertension. These transactions should be read by all investigators in the fields of experimental and clinical hypertension and by those physicians who appreciate a moving account of sometimes brilliant and more often painstaking elucidation of the fundamental mechanisms of hypertension and cardiovascular and renal pathophysiology.

The Integrative Action of the Nervous System. By Sir Charles Sherrington, O.M. With a new foreword by the author and a bibliography of his writings. New 1947 edition. Cloth. Price, \$6. Pp. 433, with 85 illustrations. Yale University Press, New Haven 7, Connecticut; Cambridge University Press, Bentley House, 200 Euston Rd., London, N. W. 1, [n. d.]

This reprinting of one of the outstanding classics of all physiologic literature is most welcome. This monograph first appeared in 1906 as the expanded presentation of a series of lectures given at Yale University as the Mrs. Hepsa Ely Silliman Memorial Lectures in 1904. It was subsequently reprinted in 1911, 1914, 1916, 1918 and 1920. In the more than a quarter of a century which has elapsed since the last reprinting it has often been difficult to obtain. This has been unfortunate, for although it will soon be a half century since these lectures were given and longer since some of the experimental work on which they were based was performed, the book maintains a remarkable vitality for all modern students of the nervous system. No single person has had greater influence on the development of neurologic science and neurologic thought than has Sir Charles Sherrington. This book contains much of his original observations and the theses based thereon.

The Physiological Society (of Great Britain) is to be congratulated on having made this work again available. It is particularly fitting that it was issued as a gift volume in connection with the Seventeenth International Physiological Congress of 1947, which met in Oxford, England.

This volume contains, in addition to the original text, an editorial note by the noted English physiologist Dr. Samson Wright, who has been directly responsible for the issuance of this reprinting, and a new foreword by Sir Charles, as well as his *curriculum vitae*.

The Rotunda Hospital 1745-1945. By O'Donel T. D. Browne, M.B., M.A., M.A.O., King's Professor of Midwifery, Trinity College, Dublin. Cloth. Price, \$11. Pp. 286, with 45 illustrations. Williams & Wilkins Co., Mount Royal & Guilford Aves., Baltimore 2, 1947.

The history of the Rotunda Hospital, covering a period of two hundred years, represents a panorama of the development of modern obstetrics. The hospital was founded on March 15, 1745 by Bartholomew Mosse as the Dublin Lying-in Hospital for Poor Women in George's Lane. Mosse's primary objectives for the hospital were to help the poor lying-in women of Ireland and to provide a teaching center in midwifery for doctors, midwives and nurses. These purposes were fulfilled admirably during its long lifetime.

The story of the Rotunda is unfolded in a series of chapters devoted to the work of each of the masters of the hospital. Many of them made important contributions to the hospital and to the development of obstetrics. These great masters helped to shape the course of the specialty. In a summary of the outstanding masters, Mosse, the founder, was a man of vision and dauntless energy who saw the fruition of a great idea. Ould, who followed Mosse, wrote a book in 1741. He made pertinent observations on labor in women with contracted pelvis and on the third stage of labor. Clarke instituted measures for the ventilation of the wards of the hospital. He was the first to realize that there was danger of infection in placing two puerperal women in the same bed. These simple measures decreased the number of fatalities from puerperal sepsis. Labatt and Collins continued the interest in puerperal fever. During their régimes active measures were taken to clean and disinfect the wards by the use of lime washings and chlorine fumigation. Each ward was closed after the occupants

were discharged, thoroughly cleansed and allowed to be idle for some days. Neither master had the vision of Holmes or Semmelweis, but they made progress in the prevention of the dread puerperal fever. The first comprehensive report of the hospital was published in 1835.

Following these masters there appeared to be a great void in the history of the hospital which lasted almost fifty years. Little progress was made. Then followed Macan, Smyly and Tweedy, who brought new life into the old institution. Their interest in eclampsia gained wide recognition.

Thus each master left his mark, small or great, on the history of a great institution. Surely obstetrics has come a long way since the establishment of this famous hospital two hundred years ago. This can be noted best in the graph at the end of the book showing the number of deliveries and the maternal mortality throughout the years.

The book will be fascinating reading for all those interested in the history of obstetrics.

The Medical Annual: A Year Book of Treatment and Practitioner's Index. Editors: Sir Henry Tidy, K.B.E., M.A., M.D., and A. Rendle Short, M.D., B.Sc., B.Sc., Contributors: T. Anwyl-Davies, M.D., F.R.C.P., and others. Sixty-Fifth Year, 1947. Fabrikoid. Price, \$7. Pp. 464, with 126 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44 Triangle West, Bristol 8, England; Simpkin Marshall, Ltd., London, 1947.

Here is another edition of the time-honored Medical Annual, a British publication representing a compilation of recent advances and new thoughts on disease. Subjects are discussed in brief, giving a summary of the present day concept of the disease or disorder together with pertinent articles in the medical literature. On the whole a thoughtful and comprehensive review is presented of current scientific medical practice.

On page 51 under the heading "Clinical Entities Frequently Missed" mention is made of retention with overflow, genito-crural, osteitis pubis, referred renal pain, differential diagnosis between renal colic and acute appendicitis and ectopic ureter; however, it is difficult to know just why these five heterogeneous subjects were classified under that heading.

A practitioner's index of the new pharmaceuticals, diets and medical-surgical appliances is a welcomed addition to the back of the book, as is a list of the recent books published during the year. The carefully compiled general index makes the book useful for ready reference on various medical subjects.

In view of the continued paper and labor shortages, the publishers are to be commended for the production of this well bound, easily readable volume with suitable illustrations and references that cover the recent developments in the medical fields.

* **Cold Spring Harbor Symposia on Quantitative Biology. Volume XII: Nucleic Acids and Nucleoproteins.** Cloth. Price, \$7. Pp. 279, with illustrations. Published by the Long Island Biological Association as part of the work of the Biological Laboratory, Cold Spring Harbor, Long Island, New York, 1947.

The present volume records the latest advance in the chemistry and biology of nucleoproteins made by laboratories in this country and abroad. The reviews are thorough, authoritative and of fundamental importance. They are of most value at present to workers in genetics, virology, bacteriology and the fields of protein metabolism. It is, however, possible to predict that the practice of medicine will be affected by further research in this field. Thorell, from Caspersen's laboratory, has demonstrated changes in the nucleic acid content of the cytoplasm during the development and maturation of leukocytes and red blood cells. Maturity can now be expressed in chemical terms; which marks an advance in cell physiology. From the same laboratory, Hyden reports on protein and nucleic acid changes in nerve cells during stimulation and during the course of infection with virus. Pollister outlines some of the histochemical methods by which it is possible to gain quantitative insight into the nucleic acid and protein contents of histologic preparations. The foregoing are examples of the type of subject discussed in the twenty-five reviews comprising this volume.

The fields covered are, at present, on the periphery of medicine, but promise to invade it soon. For those active in research in the basic sciences the information contained in this volume of the Symposia is of the highest value.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THIS WILL BE OMITTED ON REQUEST.

RECURRENT PNEUMONIA

To the Editor:—An otherwise healthy boy 6 years old has in the past had numerous attacks of pneumonia, usually between November and April. During the past winter he had two attacks of virus pneumonia and one of bacterial pneumonia with complete recovery. No basic etiologic factor for the recurrent pneumonia has been demonstrated. Would he be benefited by a change to an area where the "common cold" is not so prevalent? What are the most suitable areas in the United States?

M. D., New York

ANSWER:—There are persons who have repeated attacks of pneumonia over many years for which no cause can be found and for which little can be done prophylactically. Pneumonia is said to recur more often than any other infectious disease. The literature is reviewed in Heffron's book (*Pneumonia*, New York, The Commonwealth Fund, 1939, p. 533). In such instances it is always necessary to exhaust every diagnostic possibility, bearing in mind possible allergy and congenital or other defects which hinder normal pulmonary drainage. Bronchiectasis is unlikely in a child of 6 but must be kept in mind. If, as in the case mentioned, the attacks usually occur in cold weather, it is reasonable to assume that migration to a warm climate would be helpful (Reimann, H. A.: *Viral Infections of the Respiratory Tract; Their Treatment and Prevention*, J. A. M. A. 132:487, 1946). There is no place in the world where under average circumstances "colds" and virus pneumonias do not occur occasionally (*Medicine* 26:167 and 185). The common cold may not be quite so prevalent in the Southwestern states, but here the possibility of exposure to coccidioidomycosis exists. Although this is probably not a serious risk, even that could be avoided in the more humid Southern states.

DYSMENORRHEA

To the Editor:—A patient suffers from severe dysmenorrhea. The patient is white, aged 33, having symptoms of circulatory collapse, blood pressure of 80 systolic and 40 diastolic, profuse sweating, nausea, vomiting and severe pain. These symptoms become progressively worse each month for three months; the cycle then repeats itself. The patient is a nullipara; a gynecologic examination did not reveal any abnormality. Her weight is 144 pounds (65.3 Kg.), pulse rate 80 and normal blood pressure 120 systolic and 80 diastolic. Hemoglobin was 95 per cent and basal metabolic rate minus 12. Evidence of neuroasthenic symptoms or history is absent. The patient is being treated with analgesics during menstrual periods. Dysmenorrhea with circulatory collapse lasts from twenty-four to thirty-six hours. What assistance can you offer in this case?

S. M. Abbey, M.D., Bronx, N. Y.

ANSWER:—The association of circulatory collapse with dysmenorrhea is most unusual. An attempt should be made to prevent the pain rather than treat it after it occurs. One of the simplest ways to try to prevent dysmenorrhea is by means of estrogens or androgens. The estrogens are simpler, less expensive and more often effective in preventing severe pain at the menses. The simplest form of estrogen therapy is a 1 mg. tablet of diethylstilbestrol by mouth every night for sixteen nights beginning on the third night of menstrual bleeding. If she cannot tolerate diethylstilbestrol, she should be given two injections of estradiol benzoate in oil (1.66 mg. per dose) intramuscularly a week apart during the first half of the menstrual cycle, as first recommended by Leo Wilson. The purpose of this therapy is to suppress ovulation, because it is almost certain that functional dysmenorrhea occurs only in ovulatory cycles in the presence of a functioning corpus luteum. Of course, this treatment will relieve the pain of only one menstrual cycle; hence this medication must be repeated each month. If this treatment is carried out for a number of successive months the menstrual cycles may be disturbed and the amount of bleeding may be increased. To obtain permanent relief, a pelvic sympathectomy should be done; this operation yields almost perfect results in women relieved by estrogen therapy. In this case as in nearly all cases of severe functional dysmenorrhea, there is a large psychic factor which must be taken into consideration. Psychotherapy is of great help.

ETHYL CHLORIDE ANESTHESIA

To the Editor:—Is it safe to use an ethyl chloride spray on a mask, as an induction agent for open drop ether?

Robert C. Tavlin, M.D., Moreland, Okla.

ANSWER:—The question is difficult to answer statistically. Safety is largely a factor of the knowledge, skill and experience of the administrator. Ethyl chloride is believed to have pharmacologic effects similar to those of chloroform. Hence it may affect the heart directly and cause primary cardiac failure. The boiling point is low and the vapor of ethyl chloride is less irritant than chloroform or ether. It can therefore volatilize rapidly and pass rapidly through the lungs to the blood and tissues. If intelligently used ethyl chloride is relatively safe. The following precautions are helpful. 1. The patient should have a competent heart and normal breathing with freely patent air passages. 2. Control of dosage is more accurate in drops than in a spray. (Drops from the usual container can be secured either by prechilling or by removing the glass tip.) 3. When breathing is deeply depressed or suddenly changes in character administration should be interrupted. 4. Changes in the character of the pulse and the color of the skin should be observed continuously and administration abandoned at the first evidence of circulatory embarrassment.

When nitrous oxide or other pleasant means of induction are available, few experienced anesthetists precede the administration of ether by ethyl chloride.

TATTOOING

To the Editor:—An article in the February Catholic Digest by Mary Whiteford starts out with this paragraph: "Tattooing is no longer merely a device to hallmark the swash-buckling sailor. Its practical value has raised it to the status of a science. The Chicago tattooist, Tatts Thomas, who works with a group of doctors, says the greatest value of modern tattooing is its effectiveness in cases of slight disfigurement that are not important enough for plastic surgery. 'Lots of fellows come home from service with scars that make them self-conscious but they don't have the time or money eradication by surgery would require. I develop a pigment the same color as the patient's skin, and the scar can be made almost invisible by tattooing.'" Can you advise me whether or not there is any basis in fact in this article, whether or not Mr. Thomas is an ethical person to whom we might refer a patient? Can you inquire and find out whether he has had any experience in covering up vitiligo?

M. A. Shillington, M.D., Glendive, Mont.

ANSWER:—Those engaged in plastic surgery occasionally use the method of tattoo to mask a flat scar or a portwine mark by inserting skin-colored pigments into them. The method has a limited usefulness, however, because the technic is somewhat complicated and the results are not always satisfactory. The results in vitiligo are even less satisfactory. Vitiligo is usually progressive, lesions enlarge and new ones develop. In the summertime when the surrounding normal skin becomes tanned, the patches of vitiligo are by contrast much more noticeable than in wintertime. For these reasons one would not expect tattoo to benefit vitiligo. Even "Tatts" Thomas was quick to say that the results were unsatisfactory in the few cases of vitiligo that he had "fooled with." His studio, incidentally, is located in an amusement "arcade" and is hardly the place for a physician to refer a patient. Mr. Thomas does not pretend to anything but a tattoo parlor for the "purpose of decoration."

PARALYSIS OF VOCAL CORD

To the Editor:—A white boy, aged 17 years, experienced hoarseness about three months ago for the first time. About a week later he had symptoms of an infection of the upper respiratory tract which lasted about three weeks. The hoarseness persisted and became slightly worse. He consulted an ear, nose and throat specialist who stated that he had a paralysis of his left vocal cord. His past history is essentially negative with a history of routine immunizations against diphtheria. History of rheumatic fever or exposure to tuberculosis is absent. The physical examination including a careful neurologic examination revealed no abnormalities except laryngoscopic findings. A roentgenogram of the chest by a qualified radiologist indicates that there is a low grade accentuation of marking in the right second anterior interspace without soft infiltration. Routine blood count was as follows: white blood cells, 7,000; polymorphonuclear cells, 63 per cent; lymphocytes, 33; monocytes, 1, and eosinophils, 3.

Harry Boatwright, M.D., Kingsport, Tenn.

ANSWER:—Instances of paralysis of the vocal cord and without discoverable cause for the condition make up nearly one half of all cases reported. If the cord is completely immobile the prognosis for recovery is poor; no more than 5 per cent regain function according to recent investigators.

As in the patient described it is the left cord which is most often involved. In unilateral involvement of the vocal cord of this type, the hoarseness generally improves with time due to compensatory activity on the part of the opposite healthy cord.

CLICKING SOUNDS IN EARS

To the Editor:—A patient, 29 years of age, received a relatively minor head injury approximately seven months ago in an automobile accident when his head struck the roof of the car. Loss of consciousness did not occur. Symptoms were limited to an episode of vertigo which lasted approximately one-half hour immediately after the accident. During the following week he experienced three or four episodes of severe headache centering around the vertex of the skull without nausea or vomiting. He did not have bleeding from the eyes, ears or nose. About two days after the accident, the patient noticed a persistent ticking of both ears. This ticking is distinctly audible to medical examiners from a distance of approximately 8 inches (20.3 cm.) from the patient. It is more distinct when the examiner's ear is placed against that of the patient. The ticking is not synchronous with the pulse or heart beat. It is about one and one-half times more rapid than the heart rate. The ears show no retraction of the tympanic membranes, no edema, no evidence of infection or any other pathologic change. The eustachian tubes are patent. Roentgenograms of the skull immediately following the accident and at later intervals reveal no evidence of fracture. How can you account for the objectively audible ticking and what is its treatment? Visible motion of the tympanic membranes is absent and the patient does not move his jaws or contract his jaw muscles to produce this ticking.

M.D., New York.

ANSWER:—Ticking or clicking sounds coming from the ear are frequently the result of spasmodic contraction of the muscles at the mouth of the eustachian tube or of the intratympanic muscles. Spasmodic contractions of the muscles are similar to the tic of muscles around the eye. Local therapy is ineffective.

Treatment should be directed toward eliminating any general nervous condition.

WHISKY ACIDOSIS

To the Editor:—This concerns persons who drink whisky with "club soda" and whisky with water. It is known that whisky has an acid reaction in the system and when taken with water this action is diluted but not changed as to acidity. On the other hand "club soda" has an alkaline reaction and neutralizes to a certain extent the acid reaction of whisky. Has anything appeared in medical literature indicating the advisability of using "club soda" with whisky when taken internally?

M.D., Ohio.

ANSWER:—"Club Soda" is a mildly alkaline water charged with carbon dioxide. The labels on the bottles indicate the presence of sodium citrate and sodium bicarbonate. The pH of a sample of "club soda" was found to be 8 compared to 7 for tap water. The total solids were but 0.1 per cent. Even if all of the solids were in the form of sodium bicarbonate the amount of alkali consumed would probably be insufficient to combat the long delayed acidosis of the whisky hangover.

DECHOLESTEROLIZING AGENTS

To the Editor:—I have a patient with coronary thrombosis and a high blood cholesterol content of 482 mg. per hundred cubic centimeters. She has been on a rigid low cholesterol diet for the last six weeks without appreciable change in cholesterol content of the blood. Is there a lipolytic substance available at present to reduce blood cholesterol?

Allan M. Ross, Darien, Mass.

ANSWER:—Unfortunately the blood serum cholesterol does not respond to a low cholesterol diet in a predictable fashion. In some instances it is reduced; in others it remains unchanged. Recently Herrmann (*Am. Heart J.* 33:711-712, 1947) reported using choline, methionine and inositol as decholesterolizing agents and obtained a moderate reduction in cholesterol in many cases. However, experience with these agents is still limited and more work will be necessary before their role is established.

RHEUMATIC FEVER

To the Editor:—A boy patient 8 years old has a subfebrile temperature every day, between 99 and 100 and sometimes reaching 100.4 F. His sedimentation rate was 25 and white blood cell count 10,200. A diagnosis of rheumatic fever was made, and I started treatment with salicylates and rest in bed. The temperature was affected little but the sedimentation rate came down to 14 and the white cells to 9,000. Signs of heart disease are absent. This treatment is not satisfactory because as soon as he stops receiving salicylates and gets up the temperature goes back to 100.4 and 100.6 F. What do you suggest?

Giacomo Orsillo, M.D., Elmira, N. Y.

ANSWER:—The administration of salicylates frequently reduces the sedimentation rate and the white cell count and may or may not decrease the body temperature. This effect is nonspecific and has no known influence on the underlying disease process, which, in this case, may be rheumatic fever. The administration of salicylates is believed to have value in the control of pain and discomfort rather than in antibiotic or direct therapeutic effect in rheumatic fever. It is typical for the sedimentation rate and

the temperature to rise several days after the discontinuation of salicylates.

There is no known drug for the specific treatment of rheumatic fever. If the patient shows evidence of pharyngitis, tonsillitis or other infections, it is recommended that he receive a course of penicillin as a therapeutic trial for at least a week. It is recommended that 100,000 units be injected, intramuscularly, every four hours during this period. As long as the patient has tachycardia or fever he should be kept in bed. The sedimentation rate of 25 is considered significantly abnormal and may serve as a further guide to continuing the rest in bed.

PHARMACOLOGY OF GLYCOLS

To the Editor:—A recent article in *Hygeia* describes the solvent used in penicillin mist treatment of sinus infection. What solvent was used about ten years ago to make the elixir of sulfanilamide that caused a number of deaths? Has the pharmacology of propylene glycol, triethylene glycol and ethylene glycol been studied and reported and if so where? What is the toxicity of each? Is any of them safe for use in sinus treatment? Would the propylene glycol solution produce as good results in sinus treatment without the penicillin?

G. R. Wentzel, M.D., Sunbury, Pa.

ANSWER:—The solvent used in "elixir of sulfanilamide" was diethylene glycol. Since 1937 a large amount of work has been published concerning the pharmacology of the glycols. Among the more comprehensive papers are the following:

Hanzlik, P. J., and others: Toxicity, Fats and Excretion of Propylene Glycol and Some Other Glycols, *J. Pharmacol. & Exper. Therap.* 67: 107, 1939.

Hanzlik, P. J.; Lehman, A. J.; Van Winkle, W., Jr., and Kennedy, N. K.: General Metabolic and Glycogenic Actions of Propylene Glycol and Some Other Glycols, *J. Pharmacol. & Exper. Therap.* 67: 114, 1939.

Newman, H. W.; Van Winkle, W., Jr.; Kennedy, N. K., and Morton, M. C.: Comparative Effects of Propylene Glycol, Other Glycols and Alcohol on the Liver Directly, *J. Pharmacol. & Exper. Therap.* 68: 194, 1940.

Van Winkle, W., Jr.: Quantitative Gastrointestinal Absorption and Renal Excretion of Propylene Glycol, *J. Pharmacol. & Exper. Therap.* 72: 344, 1941.

Morris, H. J.; Nelson, A. A., and Calvery, H. O.: Observations on Chronic Toxicities of Propylene Glycol, Ethylene Glycol, Diethylene Glycol, Ethylene Glycol Mono-Ethyl Ether, and Diethylene Glycol Mono-Ethyl Ether, *J. Pharmacol. & Exper. Therap.* 74: 266, 1942.

Fitzhugh, O. G., and Nelson, A. A.: Comparison of Chronic Toxicity of Triethylene Glycol with That of Diethylene Glycol, *J. Ind. Hyg. & Toxicol.* 48: 40, 1946.

Propylene glycol has about the same toxicity as glycerine. About two thirds of the administered glycol is excreted by the kidney and one third converted to lactic acid in the body and either burned or used to form glycogen. Triethylene glycol is somewhat more toxic than propylene glycol, but in the amounts used for air sterilization the margin of safety appears to be high.

Ethylene and diethylene glycols are highly toxic. Ethylene glycol is converted to oxalic acid in the body and direct damage to liver and kidney results from the action of this metabolite. Diethylene glycol is not metabolized but is directly toxic to the kidney and liver.

Regarding the use of the propylene glycol solution without penicillin, it is possible that some antibacterial effect would have been seen, since propylene glycol is known to have an antibacterial action. Whether the results would have been comparable to those of the penicillin-glycol mixture cannot be predicted.

ATROPINE IN MUMPS

To the Editor:—Is there contraindication to the use of atropine sulfate to control salivary secretion in epidemic parotitis fifteen minutes to one-half hour before mealtime so that the patient may partake of food without the usual associated pain?

D. G. Saxman, M.D., Mechanicsburg, Pa.

ANSWER:—Usually pain occasioned by eating during an attack of epidemic parotitis is not sufficiently severe to require medication. However, no serious objection exists to prescribing atropine sulfate if salivary secretions are excessive. It is often contended that atropine is not of value in the treatment of mumps.

MONGOLIAN IDIOCY

To the Editor:—In reply to the query concerning the distinction between mongolian idiosyncrasy and cretinism (*The Journal*, January 10, p. 146), you fail to mention the use of dermatoglyphics. According to the preliminary report on the work being done by Harold Cummins and R. V. Platon (*Mongolism: an Objective Early Sign*, *South. M. J.* 33: 925-928 [Dec.] 1946), palmar dermatoglyphics has substantial value for objective recognition of mongolism. Their diagnosis was accurate in about 92 per cent of a group of 83 cases, including some normal controls. In view of this showing, the possibilities of this objective early sign should be more widely known and employed.

PLACE OF NEUROANATOMY IN THE MEDICAL SCIENCES

Chairman's Address

A. R. VONDERAHE, M.D.
Cincinnati

It is fitting that once in a decade or so the science of the structure of the nervous system be recognized, that its achievements and the methods be noted and that its place in the assembly of the medical sciences be once again defined.

Perhaps any topic concerned with anatomy as such may seem somewhat strange when presented to a gathering of psychiatrists, neurologists and neurosurgeons. This, I like to think, is due to the notion that, after all, anatomy is a fairly well seasoned science with nothing very exciting to contribute, rather than to the opinion that, in the light of the new trends in medicine wherein the psyche also requires time for study, anatomy does not offer a full measure of utility. Indeed, it has been suggested that neuroanatomy may be represented by a reading acquaintance rather than by direct study of the body structure. It is known to many of you that this is not spoken lightly. It is truly a first principle that all medical arts have basic sciences. That a basic science of clinical neurology is the anatomy of the nervous system is obvious; it has been equally obvious to representatives of the American Psychiatric Association in planning training programs that the anatomy of the nervous system is a science basic also to psychiatry. This was a wise and prudent decision. It is not to the best interests of any medical art to depart too far from its material substratum even though methods of inquiry and of treatment are discovered that can fill the practitioner's time completely. Occasional practitioners may certainly, and with much benefit to all, give their full time to a purely psychologic study of the ills of mankind; but such immaterialism would be fatal, if adopted, as a principle for all to follow. Wise are they who, in the practice of psychiatry, dip from time to time into the clear well of morphology and drink deeply again of physical reality. Befitting to a psychiatrist is the recognition of the value of cultivating the anatomic sciences; the price of abandoning this point of view would be a new mysticism and a return to the emotionally charged methods of treatment and diagnosis that preceded the influence of Galen. Study the psyche and the soma too. There is

adventure in both; but the great and ancient tradition of medicine lies more surely with a view that includes the soma.

Aristotle squarely faced this issue about two thousand years ago. His view may be worth looking into again. In Homeric Greek the word *soma* refers to a cadaver, a dead body. What then is the psyche? To Aristotle it represents the sum total of activities that distinguish the living man from the dead man. There is something about working in the dissecting room and with histologic material prepared from dead tissue which serves to emphasize the distinction between living and dead. A period of life in a person followed by death is certainly a dramatic change and presents a difference fundamental enough to be the basis of a distinction. Using the Aristotelian concept, then, the term *psyche* would refer to the whole of living activity—not merely to mental activity but to all the differences that distinguish the living man from the corpse. In this way one may avoid the disturbing dichotomy which has dogged the tracks of scientists from the time of Descartes. Here is a formula for considering man as a whole living unit, the psyche not separated from the soma but the two forming an integer, a living man. Soma and psyche, then, are not actually separated, but only separable for the purposes of separate study. In the light of this view, the brain and the rest of the nervous system are not taken to be actually set apart from other structures of the body; it is the whole actively functioning living body that includes the psychologic component. Thus, the living heart and the living stomach are as important psychologically as the living brain. In the brain certain functions come to a more critical focus; but the status of the gastrointestinal tract also enters into the processes of thinking—indirectly, of course, but quite definitely.

Futile controversies setting the psyche apart from the soma, setting the mind apart from the body, can be simply and easily discarded by giving our attention to the living man as distinct from his dead counterpart. Neuroanatomy extends the hand of good will by including functioning structure in its concepts. With a great measure of credit due the studies of American investigators, the anatomic substratum of such psychologic activities as perception, volitional movement and emotion is sufficiently known to supply a basis for global functioning in an integrated living unit. Anatomists and physiologists have joined hands in elucidating the structure, connections and functions of the nervous system, so that the mechanism of the cerebral cortex, the thalamus and the striatum are sufficiently known to provide a basis for the unitary activity with which psychology deals. The anatomic substratum of

Read before the Section on Nervous and Mental Diseases at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

thought, of emotion and of movement, distinguishable one from the other, yet flowing as in a stream and joined in the total purposive activity of a living unit, is fairly well known to us, and the underlying circuits within the central nervous system for carrying on such a flow of living activity are being demonstrated. Neuroanatomy thus provides the basic structural unity needed for the total harmony which is properly called integration.

CLINICAL NEUROLOGY

The role of the nervous system may be considered from two aspects: the role of the nervous system with respect to all organs of the body and the role of the nervous system as it relates to the specialty of clinical neurology. For completeness of knowledge in any specialty of medicine and surgery, knowledge of the relation of the nervous system to the organs concerned is required. Neurology, therefore, in its broadest aspect as the study of the structure and function of the nervous system, enters into all other special fields. It presents such a comprehensive base that it is not surprising to find that the delimitation of the field assigned to the specialty of clinical neurology should be difficult. Clinical neurology is interested in the whole of the anatomy of the nervous system, but treats only some of the diseases of the nervous system. This is at the root of the perennial mystery that surrounds the boundaries of clinical neurology. Considered anatomically, every special field of medicine and surgery has a neurologic aspect. While anatomy of itself, then, does not serve to delimit the field of clinical neurology, it does give the neurologist a sound foundation of interest in all other organs of the body.

The exact content of clinical neurology varies from decade to decade, as various portions of the diseases of the nervous system are assigned at one time to clinical neurologists and at another to orthopedists, pediatricians, internists and dermatologists. Traditionally, clinical neurology deals with unknowns, pursues neuroanatomy and other basic sciences of its subject matter and when causes and treatments are discovered, turns the diagnosis and treatment over to the nearest related specialty. In this way poliomyelitis anterior has been turned over to pediatricians and to orthopedists, posterolateral sclerosis to internists and syphilis of the central nervous system to internists and dermatologists. At the present time, the diseases of the nervous system still assigned to the clinical neurologist include the epilepsies, the post-traumatic states, the various forms of paraplegia and migraine. Clinical neurology should assert its right to the diagnosis and treatment of neurosyphilis and poliomyelitis anterior. It would benefit immeasurably by a clear definition of its scope.

A clinical specialty tends to grow out of some distinctive and characteristic method of examination, a method in which the development of a skill will exceed that generally possible for a man engaged in other subjects. Such a distinctive method will always be the ability to perform and interpret a physical examination of the nervous system. A distinctive diagnostic instrument may be found in the electroencephalograph, which, in addition, offers new opportunities for the correlation of neuroanatomy and neurophysiology.

NEUROSURGERY

The story of the development of modern neurosurgery is one of friendly collaboration between the neuroanatomist and the neurosurgeon. As neurosurgery developed, it delved into the vast pool of accumulated

neuroanatomic material and utilized it for the devising of operative procedures and methods of diagnosis. In turn, it has contributed and continues to contribute to the sum total of neuroanatomic knowledge. Whatever may be said of the *odium medicum* existing at times between the neurosurgeon and the clinical neurologist, no shred of jealousy appears between the neurosurgeon and the neuroanatomist. Cognizant of the benefits which they confer on one another, they tend to proceed in the spirit of collaboration. The very texture of neurosurgery is woven into the field of neuroanatomy. The collaboration between the neurosurgeon and the neuroanatomist, it is reasonable to believe, will go on; nothing will serve the field of neurosurgery better than the provision for residents in neurosurgery of a completely adequate program for the study of the anatomy of the nervous system. There should be an assigned time for this study and opportunities for pursuing some special topic of anatomic study. It is to the best interests of the neurosurgeon to foster in every possible way the development of neuroanatomy in medical colleges.

PSYCHIATRY

By turning our attention away from things as they are in fact and by utilizing a device of logic, we permit ourselves to make up separate sciences of morphology and psychology. The benefits so beautifully demonstrated in the intimate connection (and the acceptance of that intimate connection) between neurosurgery and neuroanatomy are equally to be had in the association of psychiatry and neuroanatomy. Some psychiatrists are tempted implicitly to deny the need and even the existence of the material substratum of their science. The nervous system is a reality. True to his code, the psychiatrist faces the reality of the nervous system, irrespective of the apparent difficulty presented by the intricacy of its structure and its seeming remoteness from many of his methods. Knowledge of the structure of the nervous system offers to the psychiatrist the touchstone by which he may proceed to correlate psychologic data with physiologic changes and pathologic evidences of disease. For this reason, in programs for the continued advance of psychiatry it is especially appropriate that consideration be given to the fostering of basic neuroanatomic studies in relation to those programs. To the psychiatrist, the neuroanatomist must yield any limitation of the field to pure morphology and include living functioning structure in the concept of his subject.

NEUROANATOMY AND THE MEDICAL SCHOOL

Neuroanatomy, because of some remoteness from practical application, requires sponsoring in colleges of medicine. It is of sufficient scope to justify a separate academic department; but its roots are such that it thrives as a subdepartment in the broad field of anatomy. The needs for its help continually arise. It is clear that clinical neurology, neurosurgery and psychiatry have a particular interest in a vigorous growth of neuroanatomy. It is also clear that all other fields of medicine and surgery need its help, its stabilizing influence and, in particular, its role in the process of integrating each particular specialty with the whole man. There should be provision for postgraduate students in every specialty of medicine and surgery to pursue detailed investigations into that part of the nervous system which concerns their specialty—this in addition to adequate provision for undergraduate teaching and for research. This can be accomplished

only by men within the profession who see the need and give it support. It cannot be well dramatized. It must get its support from the men to whom it freely gives of its treasures, the only men who are in any way fitted to realize its scope, its place and its contributions.

CONCLUSION

Neuroanatomy gives a firm basis for coordinating all systems of the body and therefore enters into the understanding of the functioning of all systems of the body. It enters into the fundamental knowledge required for all special fields of medicine and surgery and for the final and complete skill in the practice of these arts. It is the basis of neurosurgery and is required to avoid absurd pitfalls in the practice of general surgery. It is the heart of clinical neurology and of the understanding of its syndromes. It is a portion of that soma in psychosomatic medicine and psychiatry, remote with respect to some psychologic manifestations but nevertheless real. It cannot, therefore, be reasonable to make light of this science or to neglect the pleasantly intellectual discipline of its study, but, rather, in the measure that it is fostered in medical schools, in its own family of clinical neurology, psychiatry and neurosurgery and in relation to general medicine and all the individual specialties, in that measure can completeness, thoroughness and integration in all these fields be determined.

CORONARY FAILURE

THE CLINICAL SYNDROME OF CARDIAC PAIN INTERMEDIATE BETWEEN ANGINA PECTORIS AND ACUTE MYOCARDIAL INFARCTION

A. STONE FREEDBERG, M.D.
HERRMAN L. BLUMGART, M.D.
PAUL M. ZOLL, M.D.
and
MONROE J. SCHLESINGER, M.D.
Boston

A perplexing diagnostic problem confronts the physician when his patient complains of cardiac pain too prolonged to be consistent with a diagnosis of angina pectoris but, on the other hand, not attended by the various recognized features of acute myocardial infarction. The duration of bed rest and other details of treatment, as well as the prognosis, depend on the physician's evaluation of the underlying organic and functional changes. The problem is therefore of considerable practical and theoretical moment. The syndrome of cardiac pain which is intermediate between angina pectoris and acute myocardial infarction has been referred to in previous communications¹ by the term "coronary failure." The diversity of terms used by various authors to designate this and closely similar syndromes has led to considerable confusion.

Because of lack of space this article has been abbreviated in THE JOURNAL by the omission of tables 2A and 2B. The complete paper will be found in the authors' reprints, which the authors will be pleased to send on request.

1. Blumgart, H. L.; Schlesinger, M. J., and Davis, D.: Studies on the Relation of the Clinical Manifestations of Angina Pectoris, Coronary Thrombosis, and Myocardial Infarction to the Pathologic Findings. *Am. Heart J.* 19: 1-91, 1940. Blumgart, H. L.; Schlesinger, M. J., and Zoll, P. M.: Angina Pectoris, Coronary Failure and Acute Myocardial Infarction: The Role of Coronary Occlusions and Collateral Circulation. *J. A. M. A.* 116: 91-97 (Jan. 11) 1941.

The purpose of this communication is to describe the typical features of coronary failure and to indicate the spectrum-like gradation of cases between the extremes of angina pectoris and acute myocardial infarction.

Episodes of coronary failure exhibit the following clinical characteristics (table 1): 1. There is prolonged severe cardiac pain lasting from one-half hour to many hours, usually unresponsive to glyceryl trinitrate and rest. Patients often recognize that these episodes are different in quality and that the distress is commonly more intense and of longer duration than

TABLE 1.—Clinical Characteristics of Angina Pectoris, Coronary Failure and Acute Myocardial Infarction

	Angina Pectoris	Coronary Failure	Acute Myocardial Infarction
I. Clinical manifestations			
1. Pain			
(a) Onset	Sudden	Sudden	Sudden
(b) Location	Anterior part of chest—epigastrium to neck with radiation to arms	Same	Same
(c) Quality and intensity	Vague, "pain," "pressure," "squeezing," "choking"	Same as angina pectoris but more intense; similar quality	More intense, viselike
(d) Induced by	Effort, emotion, cold	Same, but may occur at rest	No necessary relation to effort, emotion or cold
(e) Duration	97% less than 3 minutes; less than 15 minutes by history*	Prolonged; longer than 20 minutes by observation and history	Usually more prolonged
(f) Frequency	Usually frequent	Infrequent	Infrequent
(g) Response to glyceryl trinitrate	Usually striking	Unusual or temporary	None
2. Peripheral vascular collapse (hypotension, sweating, nausea)	Absent	Unusual	Frequent
3. Pulmonary edema	Absent or rare	Unusual	Frequent
4. Death	Rare	Uncommon	Frequent
II. Evidences of myocardial necrosis			
1. Fever	Absent	Absent	Frequent
2. Leukocytosis	Absent	Absent	Frequent
3. Erythrocyte sedimentation rate ²	Slightly elevated (0.75 to 1.38 mm./min. in over 50%)	Same; no progressive change usually below 1.5 mm./minute	Progressive rise, over 1.5 mm./minute in 75% of cases ³
4. Pericardial friction rub	Absent	Absent	Pathognomonic when present
5. Electrocardiograms	No change or transient changes in T waves and S-T segments (depression)	Same as angina pectoris; rarely, marked changes in QRS and S-T segment may appear but are temporary and nonprogressive	Progressive changes of typical patterns usually present; conduction defects and arrhythmias common

* Riseman, J. E. F., and Brown, M. G.: The Duration of Attacks of Angina Pectoris on Exertion and the Effect of Nitroglycerin and Amyl Nitrite. *New England J. Med.* 217: 470-473, 1937.

their usual attacks of angina pectoris. 2. Attacks are infrequent compared to the oft repeated episodes of angina pectoris. 3. The attacks may be provoked by exertion, emotion or other states in which the work of the heart is increased, but they may occur during sleep or at rest. 4. Evidences of myocardial necrosis, such as sustained leukocytosis, progressive elevation of the sedimentation rate and fever, are absent. In this study the sedimentation rate has been determined by the Rourke-Ernstene method² (normal range for older age group, 0.08 to 0.70 mm. per minute). Since most of these patients have angina pectoris, the upper limit

2. Rourke, M. D., and Ernstene, A. C.: A Method for Correcting the Erythrocyte Sedimentation Rate for Variations in the Cell Volume Percentage of Blood. *J. Clin. Investigation* 8: 545-559, 1930.

of the sedimentation rate should be extended to 1.38 mm. per minute.³ 5. Electrocardiographic changes with the attacks are either absent or minor. Rarely, transient changes similar to those seen with myocardial infarction may be present for a period of hours with a subsequent return to the pattern present before the attack. Progressive electrocardiographic changes of the types characteristic of acute myocardial infarction do not occur. 6. The blood pressure usually remains unchanged. Shock and pulmonary edema rarely occur.

REPORTS OF CASES

The following cases are illustrative:

CASE 1.—A. J. H., a physician aged 65 years, entered the hospital for the third time on Oct. 11, 1940, because of prolonged precordial pain. There was a history of generalized xanthomatosis for thirty-seven years, angina pectoris for twenty years, hypertension for at least six years and cholelithiasis and cholecystectomy six years before entry. Twelve hours before entry the patient was awakened at about 1 a. m. by a severe pain in the precordial area which radiated down both arms, causing a "paralyzing sensation." Temporary relief followed the use of glyceryl trinitrate, but the pain recurred, lasted several hours, and required the injection of morphine sulfate for relief.

Physical examination on entry revealed an elderly man lying quietly in bed. The blood pressure was 150 systolic and 78 diastolic; the heart was slightly enlarged to percussion, the sounds regular and of good quality. A systolic murmur

high power field in the sediment. A complete blood count was normal, the white cell count 6,800. The nonprotein nitrogen three days after admission was 43 mg. per hundred cubic centimeters; the cholesterol was 624 mg. Electrocardiograms obtained on admission and on the fourth and eleventh hospital days (fig. 1, A, B, C) showed no significant changes. Three sedimentation rates within the first fifteen hospital days were 1.5 to 1.6 mm. per minute.

Fig. 2 (case 1, A. J. H.).—Diagram of injected, unrolled and dissected heart. Multiple tagged sections of myocardium, from areas labeled A to L, showed minimal fibrosis.

The patient's course in the hospital was uneventful. The temperature never rose above normal. The blood pressure varied little during the first twelve days (148 systolic and 76 diastolic to 162 systolic and 90 diastolic), with greater variation in the last ten days (180 systolic and 84 diastolic to 154 systolic and 76 diastolic). On several mornings, after defecation, he had attacks of angina pectoris relieved by glyceryl trinitrate, but he experienced no other episodes of cardiac pain while in the hospital.

After discharge the patient restricted his activities and suffered occasional episodes of angina pectoris relieved by glyceryl trinitrate. He reentered the hospital ten months later with clear evidence of myocardial infarction: pain in the chest of forty-eight hours' duration, shock, pulmonary edema, leukocytosis (17,000) and electrocardiograms characteristic of infarction of the posterior wall (fig. 1, D). He died on the third hospital day.

Necropsy.—The heart weighed 675 Gm.; both ventricles were hypertrophied. There was no gross evidence of fibrosis or old infarction. Microscopically, a minimal degree of focal myocardial fibrosis and a fresh infarct were found (fig. 2).

Coronary Arteries: There were pronounced arteriosclerosis and narrowing⁴ in all three main coronary arteries as well as in branches of the left circumflex and right coronary arteries (fig. 2). A fresh occlusion, caused by an edematous atheromatous plaque, was present in the distal third of the right main coronary artery. A well developed anastomotic circulation was demonstrated.

Comment.—The episode of prolonged cardiac pain in this case was not associated with clear evidence of myocardial necrosis. The temperature and white cell count remained normal. The sedimentation rate, though moderately elevated (a not uncommon finding in patients with angina pectoris⁵), was unchanged during the period of observation. The characteristic electrocardiographic patterns of myocardial infarction were absent, and at postmortem examination no old healed infarct and little fibrosis were found. The minor electrocardiographic changes seen in this patient (fig. 1) have also been observed with hypertension and non-cardiac illnesses.⁶ The attack of coronary failure ten

Fig. 1 (case 1, A. J. H.).—A, electrocardiogram Oct. 11, 1940, shortly after the attack of coronary failure, showing left axis deviation and diphasic T waves in leads 1 and 4. The S-T intervals in leads 1 and 4 are slightly depressed. B and C, electrocardiograms of Oct. 14 and 21, 1940, showing the T waves in leads 1 and 4 somewhat more inverted. D, electrocardiogram three days before death, showing bundle branch block and right axis deviation and markedly depressed S-T intervals in leads 1, 2 and 4. The S-T interval in lead 3 is elevated and coved and the T wave in lead 3 is inverted.

was present at the apex. There was no evidence of congestive failure or shock. The temperature was 98.6 F. rectally, pulse rate 62 and respiration rate 20.

Laboratory Data.—On admission, the urine contained albumin (1 plus), with occasional white cells and 1 to 2 red cells per

4. Schlesinger, M. J.: An Injection Plus Dissection Study of Coronary Artery Occlusions and Anastomoses, *Am. Heart J.* 15: 528-568, 1938.

5. (a) Zoll, P. M.; Freedberg, A. S.; Spiegl, E. D., and Blumgart, H. L.: Unpublished data. (b) Marvin, H. M.: The Diagnosis of Coronary-Artery Disease, *New England J. Med.* 226: 251-254, 1942. (c) Freedberg, A. S., and Lewis, H. D.: The Normal Heart in Old Age, *ibid.* 231: 731-738, 1944.

months before death may have been coincident with the occurrence of fresh narrowing in the coronary system, for which compensatory anastomosis was quickly developed.

CASE 2.—E. A., a man aged 59 years, entered the hospital for the third time on Sept. 23, 1937, complaining of attacks of angina pectoris for twelve years which had increased in frequency in the previous two months. The attacks were relieved in one to two minutes by glyceryl trinitrate, but lasted one-half to one hour if glyceryl trinitrate was not taken. There were, however, no episodes lasting longer than an hour. There had been no symptoms of congestive failure. On entry the heart was enlarged, the heart sounds regular and slow, the first sound muffled and of poor quality, the second sound of good quality; the second aortic sound was not accentuated. There was moderate generalized arteriosclerosis. The blood pressure was 154 systolic and 104 diastolic.

During his first month in the hospital, the patient had many attacks of angina pectoris, averaging about three daily, relieved in one to five minutes by the administration of 1/200 grain (0.3 mg.) of glyceryl trinitrate. Five months before death, while still in the hospital, he had a severe attack, during a period of pronounced emotional stress, of substernal pain which lasted two hours and was not relieved by glyceryl trinitrate. Morphine sulfate, 1/6 grain (10 mg.), gave some relief, but had to be repeated. A complete blood count taken that day showed 5,250,000 red blood cells, 97 per cent hemoglobin (Sahli), 11,200 white blood cells, with 78 per cent polymorphonuclear cells. A white blood cell count the following day was 7,650, and two subsequent counts were normal. Four sedimentation rates varied from 0.22 to 0.6 mm. per minute. Four electrocardiograms obtained during the first eight days showed no significant changes compared with an earlier tracing (fig. 3). There was no elevation of temperature or change in the blood pressure or pulse. Twelve days later, at 2 a. m., the patient had another attack of pain in the chest lasting thirty minutes, unrelieved by glyceryl trinitrate; morphine was refused. Following this episode, there were no changes in temperature, blood pressure, heart

seen microscopically. There were no old or fresh infarcts, but the myocardium near the apex had a dusky cyanotic color; microscopically this area showed no necrosis. The valves were normal.

Coronary Arteries: There was extensive coronary arteriosclerosis (fig. 4), with four old occlusions in the main stems of the left descending, left circumflex and right coronary arter-

Fig. 4 (case 2, E. A.).—Diagram of injected, unrolled and dissected heart.

ies. The ventricles received their entire blood supply from branches of the left coronary artery proximal to the occlusions. There were no fresh occlusions.

Comment.—This case is of particular interest because all three major coronary arteries had been completely occluded for some time, despite which there were no clinical or pathologic evidences of myocardial infarction. The patient had had many attacks of prolonged pain in the chest lasting one-half hour or more and had had two such episodes while in the hospital, one of which lasted two hours. These attacks were not followed by significant changes in the electrocardiogram, sedimentation rate, temperature or white blood cell count. These episodes conform to the clinical characteristics of coronary failure, and postmortem examination confirmed the absence of healed myocardial infarction.

CASE 3.—D. R., a man aged 70 years, had had angina pectoris for twenty years. Nineteen and one-half years previously he entered another hospital because he was unable to walk one block without experiencing severe attacks of pain in the chest. The pain was occasionally transmitted down the left arm. He had had many severe attacks of substernal pain lasting one to two hours with no relief by rest. On three occasions he had been awakened from sleep by these attacks of pain.

Physical examination revealed a slightly enlarged heart, moderately sclerosed peripheral arteries and a blood pressure of 145 systolic and 75 diastolic. The sounds were somewhat distant but of normal quality; the rhythm was regular and there were no murmurs. He was discharged eleven days after admission, although still suffering from slight anginal attacks while at bed rest and more severe attacks when he was up and about.

His condition was supervised in the outpatient department of the Beth Israel Hospital during the four years preceding his death. The attacks of angina pectoris continued unchanged until fifteen months before death, when he entered the hospital. During the previous two weeks the attacks had been particularly severe at night, and the night before entry he had had pain in the chest lasting three hours. There was no cough, hemoptysis, pleuritic pain or orthopnea. On entry he appeared moderately ill and slightly cyanotic. The temperature was 98.6 F., the heart rate 80, radial pulse rate 66, respiration rate 24. The blood pressure was 152 systolic and 92 diastolic. The heart was enlarged, the sounds distant. There were many extrasystoles, which accounted for the pulse deficit; there were no

Fig. 3 (case 2, E. A.).—A, electrocardiogram May 29, 1937 showing left axis deviation; the T wave in lead 1 is diphasic, in lead 2 is flat and in lead 4 is negative (old method). B, C, D and E, electrocardiograms of October 22, the day of the attack of coronary failure, and October 26, 27 and 29, showing minor changes in lead 4 (old method). In B and C the initial positive deflection of the QRS complex in lead 4 is minimal; in B and C the T wave is diphasic. In C, D and E the T wave in lead 3 shows late inversion.

rate or white blood cell count, and the patient was allowed out of bed and discharged one week later. He returned to the clinic, with recurrent attacks of angina pectoris, showed the signs of chronic passive congestion and, approximately five months later, died in congestive failure.

Necropsy.—The heart weighed 610 Gm. There was considerable diffuse fibrous myocarditis throughout the heart best

murmurs. There were dulness and fine rales at the bases of both lungs. There was no peripheral edema or evidence of shock; decided arteriosclerotic changes were noted in the eye grounds and extremities.

Laboratory Data.—Repeated urinalyses showed occasional albuminuria, a finding noted twenty years previously. On entry a complete blood cell count was normal with a white cell count of 8,900. The Hinton and Kahn reactions were negative. Three sedimentation rates were 0.5 to 0.6 mm. per minute. Five white blood cell counts in the first two weeks varied between 8,650 and 11,600. Three electrocardiograms during the first hospital week showed no changes from previous electrocardiograms (fig. 5).

During the first week the patient had several attacks of pain in the chest relieved by glyceryl trinitrate in about fifteen to twenty minutes, but thereafter he was free of pain in the chest. The temperature was never elevated during the hospital stay of thirty-two days. While the blood pressure was rather constant, ranging from 140 systolic and 78 diastolic to 138 systolic and 90 diastolic, occasional readings of 170 systolic and 110 diastolic or 180 systolic and 80 diastolic were obtained.

After discharge he continued to have substernal pain on slight exertion. He reentered the hospital fourteen months later, three days before death, complaining of severe precordial pain twelve hours in duration. He died in shock on the third hospital day with the characteristic clinical and electrocardiographic evidences of acute myocardial infarction.

Necropsy.—The heart weighed 680 Gm. Both ventricles were hypertrophied and showed slight diffuse myocardial fibrosis

grossly and microscopically. There was no evidence of an old myocardial infarct. There was a fresh myocardial infarct involving the posterior portion of the left ventricle and septum.

Coronary Arteries: All three major coronary arteries showed extensive arteriosclerosis and narrowing (fig. 6). Zones of narrowing were also present in branches of the left descending and right coronary arteries. An anastomotic circulation was demonstrated between the left descending and right coronary arteries. There was a fresh attached thrombus in the main stem of the right coronary artery. No old occlusions were found.

Comment.—This 70 year old man had had angina pectoris for twenty years, the onset of which was characterized by attacks of cardiac pain lasting one to two hours. In 1939 he had had an attack of cardiac pain of three hours' duration following which careful study revealed no shock, fever, sustained elevation of white count or sedimentation rate, or electrocardiographic changes. This episode and the episodes associated with the onset of angina pectoris conform to the clinical characteristics of coronary failure. The absence of healed myocardial infarction at necropsy is consistent with this interpretation.

The myocardial fibrosis seen at necropsy may have been a consequence of the episodes of coronary failure.

It is known that diffuse myocardial fibrosis is a common pathologic finding in angina pectoris, representing the end result of frequent ischemic episodes which lead to death and replacement of small numbers of muscle fibers. Similarly, in coronary failure certain of the ischemic muscle fibers may undergo degeneration and

Fig. 6 (case 3, D. R.).—Diagram of injected, unrolled and dissected heart. Multiple tagged sections of myocardium from areas labeled A to R showed slight diffuse fibrosis.

replacement by fibrous tissue. The total number of fibers or the size of the area involved, however, is not large enough to result in clinical evidence of myocardial necrosis. As in angina pectoris, the vast majority of muscle fibers in the involved area, although ischemic, evidently recover without damage.

CASE 4.—L. S. L., a man aged 70 years, had had hypertension for fourteen years and angina pectoris for eleven years. In October 1931, he first noted the onset of precordial oppression radiating to the upper part of the left arm on walking, which was relieved by rest. These attacks occurred several times daily. In June 1932, after unusual exertion one afternoon, he suffered a moderately severe attack of "angina pectoris," lasting ten to fifteen minutes and incompletely relieved by glyceryl trinitrate. An uncomfortable sense of substernal oppression and gas continued until 1 a. m., when he experienced a severe attack of substernal pain. The pain radiated to the left shoulder blade and down both arms to the wrists, lasted one-half hour and was not affected by nitrites. A heavy substernal oppression persisted for ten hours.

Physical examination showed a man propped up in bed with no signs of cyanosis or congestive failure. The heart was enlarged to the left, the rhythm regular and the rate 90. The sounds were of good quality and there was no friction rub or murmurs. The temperature was 98 F., the blood pressure 200 systolic and 115 diastolic to 190 systolic and 110 diastolic without alternation. A note by a prominent cardiologist stated, "A small coronary occlusion seems almost certain. He appears at the moment in good condition, comfortable but restless." An electrocardiogram taken four days later was similar in all respects to those seen previously (fig. 7, A, B). Conservative treatment of approximately three weeks in bed with toilet privileges was recommended. After this episode he continued to have angina pectoris on exertion and emotion.

In November 1936, approximately six years before death, he suffered a typical attack of acute myocardial infarction, characterized by severe, precordial pain lasting thirty-six hours, fever, peripheral vascular collapse and electrocardiographic changes (fig. 7, C, D) indicative of involvement of the posterior wall.

Except for continued attacks of angina pectoris and a mild cerebrovascular accident in 1938, the patient remained essentially the same until one and one-half years before death. At 3:30 p. m. on July 15, 1940, he began to have colicky pain in the left lower quadrant, dysuria, frequency and urgency due to vesical calculi. The same evening, while in bed, he suddenly

Fig. 5 (case 3, D. R.).—A, electrocardiogram, Dec. 8, 1937, showing left bundle branch block. B, electrocardiogram, Nov. 9, 1939, shortly after the attack of coronary failure (one of three identical tracings), showing no changes from A.

electrocardiographic changes. This episode and the episodes associated with the onset of angina pectoris conform to the clinical characteristics of coronary failure. The absence of healed myocardial infarction at necropsy is consistent with this interpretation.

The myocardial fibrosis seen at necropsy may have been a consequence of the episodes of coronary failure.

experienced severe substernal pain radiating to the inner aspects of the left arm, not relieved by three doses of glyceryl trinitrate. One hour later the patient felt weak and appeared somewhat restless, pale and perspiring. The blood pressure was 180 systolic and 90 diastolic. The heart sounds were good, and the rate was somewhat elevated. At this time an electrocardiogram showed decided changes with a pattern of acute injury of the basal posterior wall (fig. 7, E). The pain subsided in two and one-half hours after two injections of 1/6 grain (10 mg.) of morphine. The white blood cell count was 10,000. One week later it was 8,400 and the sedimentation rate was 0.8 mm. per minute.

The morning after the attack the patient felt well and had had no recurrence of pain; the blood pressure was 210 systolic and 104 diastolic. An electrocardiogram showed a reversion to his usual pattern (fig. 7, F). In the absence of subsequent electrocardiographic changes, leukocytosis and elevated sedimentation rate, this attack was regarded as one of coronary failure. The patient had an uneventful course, was kept in bed two and one-half weeks and then allowed to resume his usual, limited activities. He died in coma one and one-half years later, in February 1942, of a massive cerebral hemorrhage.

Necropsy.—The heart weighed 440 Gm. There was hypertrophy of both ventricles. There was an old healed myocardial infarct in the posterior basal portion of the left ventricle, measuring approximately 2.5 cm. in diameter. In addition, there were focal areas of subendocardial fibrosis in the posterior wall.

Coronary Arteries: All three main coronary arteries showed pronounced arteriosclerosis and narrowing (fig. 8). Four old occlusions were found, one in each main coronary artery and one in a primary branch of the left descending. A well developed anastomotic circulation with many dissectible channels was present beyond each occlusion.

Comment.—This patient with angina pectoris for eleven years had two attacks of prolonged cardiac pain without clinical evidences of myocardial necrosis and one attack characteristic of acute myocardial infarction. The attacks of coronary failure, in the light of the post-mortem findings, might well have been coincident with coronary occlusion. One may entertain the possibility

The absence of the clinical evidences of myocardial infarction (persistence of fever, leukocytosis, elevated sedimentation and of electrocardiographic changes) renders such an interpretation untenable.

This case illustrates several of the salient characteristics of coronary failure. The pain was more severe

Fig. 8 (case 4, L. S. L.).—Diagram of injected, unrolled and dissected heart. Eighteen tagged sections taken throughout both ventricles showed scattered fibrosis in posterior wall in addition to the old infarction.

and prolonged than that experienced by the patient in his usual attacks of angina pectoris. The attacks occurred at irregular and infrequent intervals, were attended by weakness but none of the evidences of myocardial necrosis. One of the two attacks of coronary failure followed unusual exertion and the other followed colic due to vesical calculi. It is of considerable interest that during this latter attack of pain there were conspicuous electrocardiographic changes but that the preexisting electrocardiographic pattern returned shortly after the subsidence of pain. It has been recognized that during attacks of angina pectoris electrocardiographic changes may occur similar to those following attacks of myocardial infarction; these changes, however, disappear with the subsidence of the attack of angina pectoris.⁶ In this patient a striking example of such a sequence of events was witnessed.

GENERAL COMMENT

The accumulation of knowledge regarding cardiac pain has been accompanied by a diversity of opinion concerning the applicable diagnostic terms. The confusion in terminology has resulted largely from numerous attempts to characterize more accurately those episodes of cardiac pain that are clearly neither angina pectoris nor acute myocardial infarction. Some authorities, because of the considerable variety of clinical episodes and coronary and myocardial changes, have deemed it inadvisable or impossible to differentiate the various types of cardiac pain and therefore denote all cardiac pain as indicative of "coronary insufficiency." Other authors have used "coronary insufficiency" to denote entirely different concepts. Master,⁷ for example, stated, "coronary insufficiency is a useful term when restricted to necrosis or infarction of the heart without complete occlusion." More recently, however, Master^{8a} has used the terms "coronary insufficiency with-

out acute occlusion" and "coronary insufficiency with acute occlusion." These are diagnostic distinctions which, in the light of our studies,¹ could be applied only to the cadaver. Continued use of these terms would seem to promote only further confusion; we therefore designate the syndrome of cardiac pain intermediate between angina pectoris and acute myocardial infarction as "coronary failure." This term connotes failure of the coronary circulation, however it may be produced, which is more prolonged than angina pectoris without, however, producing acute myocardial infarction.

The results of our previous studies of the clinical manifestations and pathologic finding in patients with cardiac pain forced us to abandon the usual terminology and classification of "coronary occlusion" and "coronary thrombosis" because of the frequent disparities that were encountered between such clinical diagnoses and pathologic observations. Coronary occlusion in and by itself produces no characteristic syndrome; in some cases old coronary occlusions have been found without any damage to the heart muscle and without having produced during the patient's lifetime any symptoms or signs of heart disease. Furthermore, our studies, as well as those of others,⁸ amply demonstrate that acute infarction may occur without fresh thrombi or occlusions and that fresh thrombi or acute occlusions of a coronary artery may occur without producing myocardial infarction. In actual practice, the terms "coronary occlusion" and "coronary thrombosis" have been widely employed to designate attacks of prolonged cardiac pain accompanied by evidences of myocardial necrosis; i.e., the occurrence of acute myocardial infarction, and it is therefore more accurate to employ the latter term. It is believed that much of the current debate on nosology⁹ revolves about this point. The differentiation of the causes of infarction is necessarily determined by pathologic study; acute myocardial infarction is the lesion which gives rise to the clinical symptoms and signs, regardless of the mechanisms of its production.

Observations¹⁰ in patients with angina pectoris support the prevailing concept that this syndrome is associated with transitory relative myocardial ischemia. The pathologic findings provide a basis for this concept. Practically every patient suffering from angina pectoris without evidence of valvular disease or arterial hypertension showed at postmortem examination old complete occlusion of at least one major artery; in the majority of instances at least two of the three main coronary arteries had been occluded before the terminal illness. That the heart muscle may frequently recover without structural damage if the degree or duration of

the myocardial ischemia is not too great is amply shown by the clinical characteristics, electrocardiographic studies and pathologic findings in patients with angina pectoris. Further support is afforded by experimental observations on the effect of artificially induced temporary coronary occlusions in animals.¹¹

Between the episodes of temporary reversible myocardial ischemia of angina pectoris and the attacks of irreversible necrosis of myocardial infarction lie the episodes of prolonged myocardial ischemia, which constitute the intermediate group of coronary failure. The clinical characteristics differentiating the three syndromes of angina pectoris, coronary failure and acute myocardial infarction are listed in table 1. Logically, one would anticipate a continuous gradation of cases between the two extremes of short attacks of angina pectoris without myocardial damage and massive infarction of the heart. It may be seen that the cases of coronary failure, listed in tables 2A and B, fall in various portions of the spectrum between angina pectoris and myocardial infarction. For example, the second episode observed in case 2 and the episode in case 11 approach the characteristics of angina pectoris, while the first episode observed in case 5 and the episode in case 7 lie in that portion of the spectrum closer to acute myocardial infarction. As has been pointed out in previous communications,¹ the underlying pathologic physiology of all myocardial pain is identical; the clinical and pathologic consequences depend on the duration and degree of the myocardial ischemia and not on the particular mechanism of its production.

✓ In accord with the concept that cardiac pain is due to relative myocardial ischemia, attacks of coronary failure are occasionally coincident with increased demands on the heart such as paroxysmal arrhythmia, emotion or effort; in other instances decreased coronary blood flow consequent to hypotension in shock due to hemorrhage, infection, dehydration, etc., is apparently responsible. When attacks of coronary failure occur without apparent precipitating factors or in circumstances which have not previously provoked pain, a recent reduction of coronary blood flow may be postulated. Such attacks may be due to the occurrence of acute coronary narrowing or occlusion. The exact pathologic mechanism of narrowing or occlusion—i.e., atherosclerosis, thrombosis, embolism, ulceration of an atheromatous plaque, subintimal hemorrhage or edema—is beyond determination by clinical means. Such instances of coronary failure are occasionally followed after an interval of hours or days by an attack of acute myocardial infarction. This results from final death of an ischemic area, which may occasionally be due to the propagation of a thrombus superimposed on a subintimal hemorrhage or on the ulcerated area of an atheromatous plaque. This sequence of events has been described clinically by Feil¹² and Sampson and Eliaser.¹³

Just as the intensity-time factor of cardiac pain may be considered to vary from relatively slight in angina pectoris, through more severe in coronary failure, to profound in acute myocardial infarction, the clinical reflection of myocardial ischemia varies from slight and

reversible manifestations in angina pectoris through more readily perceptible phenomena in coronary failure to striking and sustained changes in acute myocardial infarction. Thus, minor electrocardiographic changes or even patterns which, if sustained, would indicate a diagnosis of acute myocardial infarction, are witnessed as transitory concomitants of attacks of angina pectoris.⁶ Elevations in the sedimentation rate varying in duration and degree likewise have been reported in patients with frequently repeated severe attacks of angina pectoris.⁷ The finding of diffuse fibrosis, the "chronic fibrous myocarditis" described by pathologists in some instances of angina pectoris or coronary failure, may well represent the end result of the summation of repeated numerous microscopic insults during which temporary myocardial ischemia has progressed to the stage of death of small numbers of muscle fibers with subsequent fibrosis.

In coronary failure, electrocardiographic changes are usually absent or slight; in those instances representing the more severe gradations, transient and at times striking changes may be observed for some hours, followed by reversion to the previous pattern. Similarly, in the cases falling in that part of the spectrum which approaches acute myocardial infarction, slight transient fever, temporary rises in sedimentation rate and rarely leukocytosis may be observed. Between characteristic angina pectoris, characteristic coronary failure and characteristic acute myocardial infarction, these innumerable gradations will be observed, but the diagnostic criteria here set forth permit a clearer and more accurate differentiation of cardiac pain and have served as valuable guides in the clinical management of patients.

The diagnosis of coronary failure is of practical importance, for the treatment differs from that of angina pectoris and of acute myocardial infarction. Such patients are exposed to considerable hazard if, as are patients with angina pectoris, they are advised to continue or reduce only slightly their usual activities. On the other hand, prolonged bed rest may lead to undue hardship, anxiety and major complications. When a patient is first seen during or immediately after an attack of severe cardiac pain, the precise diagnosis often cannot be made. It has been our practice to confine such patients to bed and observe the course of symptoms and signs. If changes in temperature, pulse, white blood cell count, sedimentation rate and electrocardiograms do not occur or are equivocal, minor or evanescent, the patient is permitted to assume gradually increasing activity, sitting up in a chair after several days and then becoming ambulatory. In each case clinical judgment may modify the regimen, but in any event the episode will not be dismissed as an attack of angina pectoris nor will the patient be bedridden for many weeks. Should the attack of coronary failure be the forerunner of myocardial infarction, the patient will be under favorable conditions permitting early diagnosis and immediate treatment.

SUMMARY

The clinical and pathologic characteristics of the syndrome of acute coronary failure, intermediate between angina pectoris and myocardial infarction, are delineated. Seventeen cases have been presented; 4 are discussed in detail; the rest are summarized. Analysis of the group as a whole shows a continuous gradation in severity of coronary failure between the limits of angina pectoris and acute myocardial infarction.

Characteristic episodes of coronary failure consist clinically of prolonged cardiac pain more intense than

angina pectoris, unresponsive to glyceryl trinitrate and rest and without objective evidences of myocardial necrosis; sustained or progressive fever, leukocytosis, elevated sedimentation rate and electrocardiographic patterns of infarction are absent. Presumably, the underlying physiopathologic mechanism of these attacks of pain is prolonged but reversible myocardial ischemia. Correspondingly, on pathologic examination, no resultant myocardial infarction or extensive fibrosis can be found.

Coronary failure is precipitated in many instances by a specific clinically obvious factor which causes either sudden increase in cardiac work or diminished coronary blood flow; on the other hand, the attack often occurs at rest or during sleep. It seems likely that in some of these latter episodes without evident clinical precipitating factor the sudden relative diminution in coronary blood flow is due to acute narrowing or occlusion in the coronary tree.

The therapeutic management of episodes of this intermediate syndrome of acute coronary failure depends on clinical recognition and proper evaluation of the underlying physiologic and pathologic changes. The treatment of patients with coronary failure differs from that of angina pectoris and of acute myocardial infarction. They must not be advised, as in angina pectoris, to continue or reduce only slightly their usual activities, nor, on the other hand, should they be confined to bed for long periods of time as in acute myocardial infarction. Patients with prolonged cardiac pain should be observed closely for several days in order to determine whether they exhibit the clinical characteristics of coronary failure; if so, they may be permitted to assume gradually increasing activity, sitting up in a chair after several days and then becoming ambulatory.

ABSTRACT OF DISCUSSION

DR. W. D. STROUD, Philadelphia: The most that I know about coronary artery disease and collateral circulation has been obtained from the work of Dr. Blumgart and his associates. I feel from that work, if a patient with angina pectoris asks whether he is ever going to get rid of his pain, one is justified in saying that there is a possibility that he will. If adequate collateral circulation develops after the narrowing of a coronary artery or an occlusion, the pain may well disappear. I also feel that when the pain has gone and the patient feels perfectly well one should explain the development of the collateral circulation and that it is important for the heart to beat as slowly as possible for a number of weeks; hence the patient should be quiet so that the healed scar will be more efficient. If these things are explained, usually the patient will cooperate. Regarding the cases which have been presented, I should like to make one point. I am not positive that it is a good idea to get these patients with coronary occlusion around too soon. I feel in these cases of so-called coronary failure the patients should be kept either in bed or in a chair with bathroom privileges for at least two weeks. I know of 2 cases that I would have diagnosed as this type of coronary failure, in which there never was any increase in fever, sedimentation rate or leukocyte count, but in 1 instance fourteen days, and in the other case fifteen days after the episode, the electrocardiogram showed definite evidence of coronary occlusion. I think that we should be conservative in our treatment of patients who have given such strong clinical evidence of coronary occlusion before we make up our minds that they have coronary failure.

DR. ARTHUR M. MASTER, New York: Although the laboratory of the authors is hundreds of miles from ours in New York, our results have been similar. Since they are minor, it might be well to speak of our differences of opinion. The authors use the term "coronary failure" to describe episodes

between a simple attack of angina pectoris and a severe attack with myocardial infarction. It is difficult to find a name that suits all conditions and physicians but if the matter of terminology already is difficult, why add another term unless it makes for clarification and simplification? I believe that the cases of coronary failure described by the speakers fall into the classification of coronary insufficiency as used by us and other workers. We have divided acute coronary disease into two main divisions: (1) acute coronary insufficiency, which is a disproportion between the demands of the myocardium for oxygen and blood and the supply; it varies from the slight attack of angina pectoris to a severe one in which the ischemia is so prolonged or severe as to cause myocardial infarction; (2) acute coronary occlusion, which, on the other hand, we reserve for the classical attack of severe pain in the chest and in which fever, leukocytosis, blood pressure drop, pericardial rub, change in heart sounds, increased sedimentation rate are not only usually present but practically always more pronounced than in coronary insufficiency. The two can be differentiated by the electrocardiogram. We did not coin the term "acute coronary insufficiency." The pioneers abroad, particularly in Germany, and the early American workers used this term, and we felt that some recognition should be given their work. We have found the term "acute coronary insufficiency" helpful, and it has stood the test of time. The typical electrocardiographic findings in acute coronary insufficiency, which includes "coronary failure," consists of depressions of RS-T intervals and inversions of T waves. The authors showed a slide in which there was RS-T elevation in lead 3, but it is to be noted that this was an exceptional case, for myocardial infarction due to previous coronary occlusion had probably taken place as evidenced by a Q wave in lead 2 and a large Q wave in lead 3. Coronary disease need not be present in acute coronary insufficiency. In other words, in an attack of acute coronary insufficiency, or the authors' "coronary failure," the arteries may be perfectly normal.

DR. ROBERT L. LEVY, New York: The work of Drs. Blumgart and Schlesinger and their associates has contributed to our knowledge of the natural history of atherosclerosis of the coronary arteries. Their excellent studies with the injection-dissection technic have made clear the insidiously progressive character of the sclerotic process. They have shown how extensive the lesions may be in the absence of serious symptoms because of the gradual development of the pathologic changes and the parallel growth of a collateral circulation. The type of cardiac pain which has been described presents a nice problem in clinical diagnosis and judgment. But it does not deserve a special designation. Accurate terminology is not mere quibbling, for it promotes clear thinking and intelligent therapeutic procedure. Any disorder which interferes with the adequate flow of blood through the coronary bed causes coronary insufficiency. Coronary insufficiency is a functional disturbance in which the supply of oxygen to the myocardium is insufficient to meet the demands of the heart, in terms of work. It may be caused by a variety of factors which bring about this disproportion and result in cardiac ischemia. It manifests itself most frequently as pain, but may appear in a different form such as pulmonary edema or a cardiac arrhythmia, or even as sudden death. The correlation of symptoms and signs with anatomic changes makes possible the definition of certain distinctive syndromes. The picture which the authors have drawn appears to be that of coronary insufficiency due to partial or complete atherosclerotic closure of a coronary artery, not associated with thrombosis and not followed by the usual evidences of infarction. In some of their cases, to be sure, a slight transient rise in the leukocyte count and sedimentation rate suggested the possibility that minute areas of heart muscle had undergone necrosis. The relatively brief duration and reversible character of the disturbance were due to the presence of ample collaterals. It is logical to regard coronary atherosclerosis as a single pathologic process, appearing, in its various phases, as intimal thickening, subintimal hemorrhage, abscess formation, partial occlusion or complete closure. The occurrence of thrombosis is but one episode in the chain of events. The injury to the myocardium is manifested by infarction and fibrosis. Similarly,

there is a single functional disorder, coronary insufficiency, which likewise varies in its manifestations according to the nature and extent of the structural changes in the arteries and muscle of the heart. This concept is in accord with current knowledge and helps to simplify our understanding of a complex group of conditions. Studies such as this, which interpret the clinical features in terms of the pathologic lesions, aid in furnishing the basis for the rational management and effective treatment of patients.

DR. JOSEPH T. WEARN, Cleveland: Dr. Freedberg mentioned emotion as one of the causes precipitating these attacks. For years, I have been interested in the fact that excitement of various sorts tended to precipitate anginal attacks and attacks of coronary thrombosis. I found a newspaper clipping of a person's sitting in a poker game who held four aces. Before he was able to put his chips into the pot, he died of coronary occlusion. Since then, a number of persons have sent me clippings of sudden deaths of precipitated angina as the result of emotion or excitement. A recent one in my own experience will illustrate the effect of emotion. This patient was subject to anginal attacks and was driving along a street in Cleveland when a truck cut in front of him and dented his front mud guard. He decided what he was going to say to the truck driver, but as he drew up along side, he was seized with an attack of pain in the chest over his heart and had to slow down and pull up at the curb and allow the truck to pass on. Another instance was that of a wife and a husband playing bridge. The husband did not play the hand as his partner thought he should. As soon as the cards were thrown to the middle of the table, she started to tell him how he should have played it, but was seized with pain over the heart which was later shown to be due to coronary thrombosis.

DR. HERRMAN L. BLUMGART, Boston: Diagnostic classification, if it is to be significant, must be based on clinical and physiopathologic facts. Classification is justified only if it leads to more accurate diagnosis and to more accurate treatment. If these objectives are achieved, the precise choice of words is of relatively small moment. Our preference for the term coronary failure is due mainly to the fact that "coronary insufficiency" has been used by so many persons to designate so many syndromes, including angina pectoris, acute coronary occlusion, acute myocardial infarction and acute coronary thrombosis, that the term "coronary insufficiency" has ceased to have precise meaning. We have used the term "coronary failure," hoping to clarify the situation somewhat. If it were to be called "Syndrome X" or "Y" or "A," or if every one were to agree that this intermediate syndrome should be called "coronary insufficiency," we would concur. Our studies during the past decade were undertaken because clinical diagnoses no longer conformed to the facts disclosed by the improved methods of Dr. Schlesinger. The clinical classification of cardiac pain into three categories—that is to say, angina pectoris, coronary failure and acute myocardial infarction—has been the result of a detailed pathologic and clinical study of almost a thousand cases. The clinical criteria which have been set forth permit one to predict with high accuracy the actual pathologic findings within the heart disclosed post mortem. Not only is diagnosis more accurate but the regimens of treatment for each of these three categories are importantly different and distinctive. We would agree with Dr. Stroud and others in being conservative in treating patients with coronary failure. We agree that bed rest of perhaps ten days or two weeks may be indicated in some of these patients. Our studies, which have now been corroborated by others, have shown that narrowing of the coronary arteries stimulates the development of compensatory anastomotic circulation. In the presence of anastomotic circulation, a sudden narrowing or an acute, fresh occlusion, we believe, may occur occasionally without producing acute myocardial infarction. The experimental delineation of that situation has been reported previously in 1942, at the Association of American Physicians (*Tr. Am. Physicians* 57:152, 1942). There is no specific electrocardiogram of coronary failure. Even in angina, the attack may show elevation of the S-T segment rather than depression.

A NEW VEHICLE FOR PARENTERAL REPOSITORY PENICILLIN THERAPY

The development of a simple and efficient method for maintaining and prolonging an effective plasma level of penicillin and for reducing thereby the number of intramuscular or subcutaneous injections necessary has been the subject of various investigations during the last few years. In all instances, it was attempted to slow the absorption of the penicillin from the site of injection by incorporating the antibiotic either into a mixture of wax and oil¹ or into water in oil emulsions² or into an oily vehicle³ or into complex vehicles containing vasoconstricting agents.⁴ The greatest success in this respect has been attained by the penicillin-wax-oil mixture of Romansky. However, the high melting point and the considerable viscosity of this preparation require special syringes, and the occasional occurrence of painful indurations and abscesses at the site of the injection is an undesirable complication.

An injectable preparation of penicillin, which can be handled at ordinary room temperature because of its fluidity at room temperature, not requiring special syringes for injection and which does not give rise to appreciable local untoward reactions, while possessing therapeutic properties equal or superior to the existing agents, would represent a distinct advance.

It is felt that the preparation to be discussed is a definite step in this direction.⁵ The observation that small doses of epinephrine suspended in oil exert a strong delaying effect led us to incorporate potassium penicillin into a vehicle of this composition.

The quantity of epinephrine added to the oil was kept sufficiently low to assure a prolonged local vasoconstrictor action without causing any systemic vasoconstrictor effect. Extensive experimentation with this preparation on animals as well as observations in man showed that the considerable slowing of the absorption of the penicillin from its intramuscular or subcutaneous depot into the general circulation was not essentially due to the oily character of the vehicle, as a prominent delaying action was caused by the prolonged ischemic effect of the epinephrine gradually released from its oily base. The following composition was found generally to be the most useful and efficacious one: crystal-

line potassium penicillin, 300,000 units; epinephrine, 0.3 mg., and vegetable oil, 1 cc.

The following experimental data on man and dogs demonstrate the pharmacologic properties of this preparation and indicate its presumptive therapeutic effectiveness.

EXPERIMENTAL PROCEDURE

Technical Data.—The preparation used was available in ampules containing 1 cc. of oily medium for the 200,000 and 300,000 units of crystalline potassium penicillin doses and 2 cc. for the 400,000 and 600,000 unit doses. After brief shaking of the ampule for resuspending the sedimented penicillin, the preparation was drawn into an ordinary syringe (2 or 5 cc.) through a 20 or 21 gage needle. It was injected into the muscle of the buttocks without any difficulty. Blood for the determination of the penicillin level was removed at varying intervals from the jugular vein of the dogs and from the cubital vein of man. The serial dilution method of Rammelkamp⁶ was employed for the bioassay of the serum, cultures of *Streptococcus hemolyticus*, type A, group 3, being used as the test organism.

Experiments on Dogs: Mongrel dogs weighing from 7 to 15 Kg. (average around 10 Kg.) were given intra-

Chart 1.—Average penicillin serum levels following intramuscular injection of "intracillin" in dogs.

muscular injections with the penicillin-epinephrine-oil preparation ("intracillin" Warner) containing 200,000, 300,000 and 400,000 units of penicillin, respectively, and epinephrine in quantities varying from 0.1 to 0.4 mg. per dose. For purposes of control, similar amounts of penicillin were administered in isotonic sodium chloride solution and suspended in oil. A commercial calcium penicillin-beeswax-oil preparation also was given for comparative purposes. Chart 1 illustrates the results obtained as to the height and duration of demonstrable blood penicillin level and averaged for the various groups composed of a total of 66 dogs.

Although there occurred distinct variations of the blood penicillin responses among the individual animals to the same type of preparation, it is obvious that there was a considerable prolongation of the demonstrable penicillin blood level in all animals which received the penicillin-epinephrine-oil preparation over those which were given corresponding doses of penicillin in isotonic sodium chloride solution or penicillin in oil.

Experiments in Man: A. Intramuscular administration. The experiments on man were conducted on an ambulatory basis on normal volunteers. The general procedure observed was identical with that used in the dog experiments. The various agents were injected

The data contained in table 2 demonstrate that there was not in any case a significant increase of blood pressure which could be attributed to the vasoconstrictor substance injected. This is particularly noteworthy in regard to those subjects who showed an original systolic blood pressure of 150 mm. of mercury or over, although in several subjects "intracillin" containing doses of epinephrine much higher than those present in the commercial preparation ultimately adopted (0.3 mg.) was used. Pharmacologic experiments on cats⁷ confirmed the lack of a systemic vasopressor effect of

epinephrine in oil given intramuscularly in doses six times higher than those present in "intracillin."

The evidence presented in chart 2 demonstrates that in man also the epinephrine in oil vehicle caused a considerable prolongation of the demonstrable blood

Chart 2.—Average penicillin serum levels following intramuscular administration of "intracillin" in man.

penicillin level. With doses of 300,000, 400,000 and 600,000 units of potassium penicillin, there existed a demonstrable blood penicillin level well beyond the fifteen hour mark (in contrast to the seven hour range when 300,000 units of potassium penicillin was given

intramuscularly in isotonic sodium chloride solution), while doses of 200,000 units produced a demonstrable blood penicillin level for more than twelve hours.

B. Subcutaneous administration. In view of the fact that the degree of vascularity of the subcutaneous tissue is lower than that of the muscular tissue and considering that depots located in the subcutaneous tissue are less subject to the massaging action exerted by contracting muscle tissue than those situated in the muscle tissue proper, 39 patients with gonorrhea were given subcutaneous injections of "intracillin" containing 150,000, 300,000 and 600,000 units of potassium penicillin, respectively. (This investigation was done in

7. Ercoli, N.; Hueper, W. C.; Schachter, R. J.; Schwartz, B. S., and Whitehead, M.: To be published.

cooperation with Drs. A. Cohn and B. Kornblith.) The values of the penicillin blood levels are presented in chart 3.

The duration of the demonstrable blood penicillin values at a relatively high level for a period of practically twenty-four hours is a feature of this route of administration of "intracillin" with doses of 600,000 units of potassium penicillin. Particularly noteworthy is the fact that even with doses as low as 150,000 units there was in an appreciable number of cases a demonstrable blood penicillin level fifteen hours after the injection.

Since the results reported here have been obtained on unanesthetized animals and ambulatory patients, who subject their tissue depots of penicillin to an appreciable amount of natural massage accelerating the rate of absorption, it is likely that in hospitalized patients, kept in bed during the course of the penicillin treatment, there may be a definite additional prolongation of the period during which demonstrable penicillin levels may be found in the blood.

Chart 3.—Penicillin serum levels following subcutaneous administration of "intracillin" in man.

CONCLUSIONS

The evidence presented supports the claim that the penicillin - epinephrine - oil preparation ("intracillin") besides being easily handled with syringes and needles ordinarily available, produces after intramuscular and, particularly, after subcutaneous injection an effective and demonstrable blood penicillin level for periods covering sixteen to twenty-four hours when administered with a penicillin content of 300,000 units of potassium penicillin.

ADDENDUM

A clinical study in the treatment of gonorrhea conducted by Drs. Alfred Cohn and B. A. Kornblith, of the Department of Health, City of New York, confirmed the therapeutic advantages of this penicillin preparation.⁸

These authors found that one single injection of ½ cc. of a preparation containing 150,000 units of penicillin and 0.15 mg. epinephrine cured 97 out of 100 male patients with gonorrhea. The 3 patients who did not respond to the initial injection were promptly cured with a second injection of an identical dose (½ cc. "intracillin").

Aureomycin is an antibiotic derived from a strain of *Streptomyces aureofaciens*. It is supplied as a yellow crystalline hydrochloride salt which is soluble in distilled water but somewhat less soluble in isotonic sodium chloride solutions. These solutions are acid (pH 4.5). The activity of the antibiotic deteriorates rapidly in alkaline solution at room temperature.

IN VITRO STUDIES

Aureomycin has been shown to possess antibacterial activity against numerous gram-positive and gram-negative bacteria. Beta hemolytic streptococcal strains, groups A, D, F and G, and three strains of *Streptococcus faecalis* were susceptible to the effects of 0.3 to 1.25 micrograms of aureomycin per milliliter; *Diplococcus pneumoniae* types I, II and III were susceptible to 0.1 to 0.3 microgram, staphylococci to 0.6 microgram per milliliter, strains of *Bacillus coli aerogenes* to 5.0 micrograms per milliliter; *Klebsiella pneumoniae* to 1.0 to 5.0 micrograms per milliliter, *Hemophilus influenzae* to 2.0 micrograms per milliliter, and *Brucella suis* and *abortus*¹ to 0.75 microgram per milliliter, while *Pseudomonas aeruginosa* and strains of *Proteus* were not inhibited by 20.0 micrograms per milliliter. The antibiotic appeared to be bacteriostatic rather than bactericidal except in high drug concentration. Human serum seemed to have an inhibiting effect on the antibiotic's activity, and to obtain an inhibitory concentration in the presence of 50 per cent serum about fifty times the concentration was necessary as compared with that in broth.

IN VIVO STUDIES

The acute toxicity of aureomycin was determined in mice, rats, rabbits and dogs. All mice survived a single intravenous injection of 50 mg. per kilogram of body weight. Fourteen per cent survived 100 mg. per kilogram of body weight. Seventy-seven per cent of mice receiving 3,000 mg. per kilogram of body weight in a single subcutaneous dose survived a seven day observation period. All the animals died when 4,000 mg. per kilogram of body weight was administered. Death was preceded by hyperpnea, tremors, ataxia and paresis. Areas of necrosis were noted at the local site of injection.

Hyperpnea and anorexia developed in dogs following rapid intravenous injection of 50 and 100 mg. per kilogram of body weight. Injection of 150 mg. per kilogram of body weight was followed by grunting respiration, tremors, generalized paresis, somnolence and hemoglobinuria. Death occurred six hours after the injection was given. A dog which received 20 mg.

From the Department of Preventive Medicine, Johns Hopkins University School of Medicine, Baltimore.

Aureomycin was first described by Dr. B. M. Duggar, Lederle Laboratories Division, American Cyanamid Company.

Aureomycin used in these experiments was supplied by the Lederle Laboratories Division, American Cyanamid Company.

This paper is an abstract of reports made before the Section on Biology, New York Academy of Sciences, July 21, 1948.

These investigations were supported by grants from Abbott Laboratories, Eli Lilly and Company, Lederle Laboratories Division, Parke, Davis & Company and the Upjohn Company.

1. All *Brucella* cultures were performed by Mr. Ronald M. Wood of the Laboratories of the Wilmer Ophthalmological Institute, Johns Hopkins Hospital.

per kilogram of body weight intramuscularly twice a day for nine days had decided anorexia and loss of weight. Induration, necrosis and fluctuation of the injected areas were noted. The aureomycin was administered in 1 per cent procaine hydrochloride solution.

Rats tolerated subcutaneous injections of 50 mg. per kilogram of body weight once a day for eight days, with only a slight loss of weight and mild local inflammatory reaction.

Three drops of a solution of 0.25 per cent and 1.0 per cent aureomycin borate were instilled locally into the conjunctival sac of a rabbit. No immediate or delayed reactions were noted.

At autopsy no gross or microscopic abnormalities were noted in any of the animals except for necrosis of tissue at the local site of injection. Hemoglobinuria occurred in only 1 dog which received 150 mg. per kilogram of body weight intravenously in a 10 per cent solution in distilled water. The acidity of such a large dose may well have caused hemolysis.

CONCENTRATIONS OF AUREOMYCIN IN BODY FLUIDS

The following concentrations of the antibiotic in blood serum were obtained after single intramuscular injections of 20 mg. per kilogram of body weight in rabbits and 40 mg. per kilogram of body weight in dogs. Levels of 1.25 mg. per milliliter were recorded in the serum in from fifteen minutes to one hour following the injections. No significant concentrations were obtained in the serum more than one hour after the injection was given. A dog received 20 mg. per kilogram of body weight twice a day for ten days. No significant concentrations were detected in the serum obtained more than two and five-tenths hours after the last injection was given. Serums drawn one hour after the injection was administered contained 0.3 to 1.25 micrograms of aureomycin per milliliter. The antibiotic was not detected in the spinal fluid, but high levels were observed in the urine.

When aureomycin was administered orally to a 150 pound (about 68 Kg.) man in doses of 500 mg. twice a day and 40 mg. intramuscularly every six hours, blood levels of 0.6 to 2.4 micrograms per milliliter of serum were observed one hour after an injection was given. The antibiotic produced a greenish yellow discoloration of the urine, in which concentrations of 40 to 80 micrograms per milliliter were observed.

MOUSE PROTECTION

Mice infected intraperitoneally with 10,000 lethal doses of *D. pneumoniae* type I (SVI), and *Streptococcus hemolyticus* beta (C23) showed complete clearing of the infection in the blood stream eighteen hours after subcutaneous treatment with 5 mg. of aureomycin per kilogram of body weight three times daily. When *K. pneumoniae* type A was the infecting organism, only partial sterilization of the blood stream was obtained with a dosage schedule of 10 mg. per kilogram of body weight three times daily.

The protection of mice infected with 1,000 lethal doses of *K. pneumoniae* A, *D. pneumoniae* I (SVI) and *S. hemolyticus* beta (C203) and treated with aureomycin, administered by various routes, was studied. Communal feeding was begun two days before infection and continued for five days thereafter, so that a daily dose of approximately 50 mg. per kilogram of body weight was ingested. No survivors were observed at the end of seven days except among those mice infected with *S. hemolyticus* beta (C203), in which a 70 per

cent protection was noted. Gastric intubation begun immediately after infection and continued once each day for three days protected only those mice infected with *S. hemolyticus* beta (90 per cent survivors). A single subcutaneous injection of 50 mg. per kilogram of body weight administered immediately after infection protected 30 per cent of mice infected with pneumococcus type I, 50 to 70 per cent of those infected with *S. hemolyticus* beta and 40 per cent of mice infected with *K. pneumoniae* type A. One hundred mg. per kilogram of body weight administered subcutaneously protected all mice infected with pneumococcus type I and 80 per cent of those infected with *K. pneumoniae* type A. The intraperitoneal route for administration of aureomycin was somewhat more effective than the subcutaneous route, even though treatment was instituted two hours after infection. Parallel experiments were performed in mice, employing treatment with penicillin as a control for the infections produced with the gram-positive organisms. Treatment with streptomycin and polymyxin was used as control for the infections produced by *K. pneumoniae* type A. Aureomycin when compared on the basis of mg. per kilogram of body weight dosage was as effective as penicillin when pneumococcus type I was the infecting organism. The protection achieved in infections produced by *S. hemolyticus* beta was somewhat inferior to that when penicillin was used. When all routes of administration were compared, the protection of mice infected with *K. pneumoniae* type A, and treated with aureomycin, was definitely less than that observed with polymyxin or streptomycin.

TREATMENT OF PATIENTS

Patients suffering from coli-aerogenes and *S. faecalis* infections of the urinary tract, Rocky Mountain fever (Eastern type), typhoid and brucellosis have been treated with aureomycin, which was administered orally and/or intramuscularly. The oral dosage employed varied from 10 to 60 mg. per kilogram of body weight per day, given in six to twelve doses. Intramuscularly, a total dosage of 3 mg. per kilogram of body weight per day, divided into four doses, was tolerated, but with signs of moderate local irritation. The 5 patients with Rocky Mountain spotted fever, treated on the third to the fifth day of their disease, were afebrile and asymptomatic within twelve to seventy-two hours. A patient ill with chronic brucellosis, whose blood cultures were repeatedly positive for *Br. suis*, became afebrile three days after institution of aureomycin therapy. Blood cultures became sterile forty-eight hours after treatment was begun. As of the date of reporting, these had remained sterile and the patient had remained afebrile and asymptomatic for more than two months. Infections of the urinary tract due to coli-aerogenes and *S. faecalis* have been sterilized and evidence of inflammation has disappeared when patients were treated with aureomycin by mouth.

SUMMARY AND CONCLUSIONS

Aureomycin possesses bacteriostatic and bactericidal activity against numerous gram-positive and gram-negative bacteria.

Its activity deteriorates rapidly in alkaline solution. Human serum also decreases its activity.

The LD₅₀ on intravenous injection in mice is between 50 and 100 mg. per kilogram of body weight. The LD₅₀ on subcutaneous injection in mice is between 3,000 and 4,000 mg. per kilogram of body weight. Rapid intravenous injection of 150 mg. per kilogram of body weight killed a dog and produced hemoglobinuria.

Repeated large doses of aureomycin were tolerated in rats and dogs, with moderate local reaction and some loss of weight associated with anorexia. Autopsy revealed no gross or microscopic abnormality of the viscera.

A rabbit tolerated 1 per cent aureomycin borate administered locally in the eye.

The concentrations of the antibiotic in serum ranged from 0.3 to 2.4 micrograms per milliliter. The antibiotic was not detected in the spinal fluid. High concentrations of aureomycin were noted in the urine.

Aureomycin administered to mice orally did not protect against infections produced by pneumococcus type I or *Klebsiella pneumoniae* type A, but did protect against those produced by *Streptococcus hemolyticus* beta (C203). Parenteral doses gave some protection against all three infections. Penicillin afforded slightly more protection against infections produced by gram-positive bacteria, while polymyxin and streptomycin were superior in experimental infections produced by *K. pneumoniae*.

Five patients suffering from Rocky Mountain spotted fever, 2 patients with infections of the urinary tract due to *Escherichia coli*, 1 patient with brucellosis and 2 patients with typhoid were treated, with favorable initial responses.

OCCURRENCE OF SUPERINFECTIONS DURING ANTIBIOTIC THERAPY

EMANUEL APPELBAUM, M.D.

and

WILLIAM A. LEFF, M.D.

New York

It has been frequently observed that during the course of treatment with an antibiotic a complete change in the bacterial flora may occur. In these circumstances the pathogens sensitive to the antibiotic in use disappear or become less numerous and insensitive organisms may appear in large numbers and cause a new infection. For example, when using penicillin for an infection caused by a gram-positive organism one may encounter a secondary infection caused by a gram-negative bacillus. The reverse may obtain when one uses streptomycin.

Lipman, Coss and Boots¹ described changes in the bacterial flora of the throat and intestinal tract during prolonged oral administration of penicillin. In two recent papers Weinstein² discussed the subject of new infections developing during the course of specific antibiotic therapy and reported 5 illustrative cases. Stanley³ reported a series of 5 cases in which a severe systemic infection due to *Bacillus pyocyaneus* developed during a course of treatment with penicillin and further suggested that the use of this antibiotic may have enhanced the virulence of *B. pyocyaneus*. In several papers on penicillin therapy in bronchopulmonary disease there are references to the frequent appearance of gram-negative bacilli in the sputum, but little comment in regard to the significance of this development. It is the purpose of this paper to record 2 cases of pneumococcal pneumonia treated with penicillin in which

there developed a new infection due to gram-negative bacilli and also to stress the occurrence of superinfections as an important feature of antibiotic therapy.

REPORT OF CASES

CASE 1. History.—R. C., a man aged 45, was admitted to Bellevue Hospital on Nov. 8, 1946, with the complaints of dyspnea, productive cough and tightness of the chest of three weeks' duration. The sputum was greenish but not foul. In addition, he had swelling of the legs, weakness, anorexia and loss of weight of about 10 pounds (about 4.5 Kg.).

Physical Examination.—On admission the patient was acutely ill, pale and malnourished and coughed continuously. The temperature was 103.6 F., the pulse rate 120 and the respirations 28. There was moderate cyanosis and dyspnea. The left side of the thorax showed limitation of expansion. There was dullness, modified breath sounds and fine crackling rales over the lower third of the upper lobe of the right lung and diminished fremitus and rales over the lower two thirds of the left lung. The heart was not enlarged, but had a systolic murmur at the apex. The blood pressure was 120 systolic and 40 diastolic. The abdomen was soft. There was pitting edema of both legs. There were no other striking observations. A diagnosis of pneumonia was made.

Laboratory Examination.—The red blood cell count was 2,820,000, with 7.5 Gm. hemoglobin, and the white blood cell count was 6,550, with 61 per cent polymorphonuclear cells and 39 per cent lymphocytes. The urine was essentially normal. The sputum was copious and purulent, but not foul, and showed a predominance of pneumococci II and also some staphylococci and nonhemolytic streptococci. The blood culture was positive for pneumococci II. Fluoroscopy showed an homogeneous density throughout the lower two thirds of the left lung and areas of patchy infiltration in the lower third of the upper lobe of the right lung.

Treatment and Course.—On admission the patient received 4 Gm. of sulfadiazine and then 1 Gm. every four hours. When the temperature rose to 104 F., on the second day, penicillin therapy was instituted. The patient received 40,000 units and later 50,000 units intramuscularly every three hours. On the fourth day the patient appeared toxic and showed an extension

Fig. 1.—Summary of data in case 1.

of the pneumonic process in the left lung and also showed evidence of involvement of the middle lobe of the right lung. Since the presence of fluid at the base of the left lung was suspected, an exploratory thoracentesis was done. This yielded 3 cc. of thick rusty pus, which showed on culture the presence of pneumococci II. The impression was that the aspirated material was from the lung parenchyma.

When it was shown that the isolated pneumococcus had a penicillin sensitivity of 0.01 unit per cubic centimeter, the sulfadiazine therapy was stopped and penicillin alone was used. In addition to the systemic administration of penicillin, the drug was also given by aerosol, 50,000 units ten times a day. Following the course of penicillin therapy the patient improved somewhat, and pneumococci II disappeared from the blood and

Dr. Jack Nelson and Dr. Joel J. Brenner assisted in the study of the cases.

sputum. However, a sputum culture taken on the thirteenth day revealed the presence of gram-negative bacilli, identified as *Aerobacter aerogenes* and *Escherichia coli*. At the same time the blood culture was positive for *E. coli*.

On the eighteenth day the temperature rose to 104 F., and the patient became toxic and appeared close to death, with decided dyspnea and cyanosis. Streptomycin therapy was then instituted, the patient receiving daily 2 Gm. intramuscularly and 1 Gm. by aerosol. On the twenty-third day his temperature began to drop, accompanied with general clinical improvement. It should be noted, however, that the isolated gram-negative bacillus showed a streptomycin sensitivity of 500 units per cubic centimeter.

Improvement continued until the thirty-fourth day, when the patient became toxic again and the temperature rose to 102 F. The sputum, which had diminished in quantity, now revealed pneumococci II again, but not the gram-negative bacillus. Penicillin was therefore given in addition to the streptomycin, the patient receiving 500,000 units intramuscularly daily and 1,000,000 units by aerosol. There was a prompt response to this treatment. The temperature dropped to 100 F. during the next two days and then returned slowly to normal. This was associated with general clinical improvement, a sense of well-being and gain in weight. In spite of fairly extensive residual pulmonary fibrosis, there was only slight impairment of respiratory function. The patient was in good condition at the time of his discharge on May 1, 1947.

CASE 2.—History.—E. E., an man aged 44, was admitted to Bellevue Hospital on Feb. 21, 1947, with the complaints of chilly sensation, fever, pain in the right side of the chest, cough and dyspnea of one day's duration.

Physical Examination.—On admission the patient was acutely ill, apprehensive and dyspneic. The temperature was 102 F., the pulse rate 110 and the respiration 32. The blood pressure

Fig. 2.—Summary of data in case 2.

was 110 systolic and 60 diastolic. There were dullness and bronchovesicular breath sounds over the lower part of the right lung posteriorly and in the axilla. The heart presented no abnormalities, and the results of the rest of the examination were essentially negative.

Laboratory Examination.—The white blood cell count was 26,000, with 91 per cent polymorphonuclear leukocytes. The sputum revealed a predominance of pneumococci II, together with an occasional *Streptococcus viridans* and *Staphylococcus albus*. The roentgenogram of the chest showed a pneumonic consolidation of the middle lobe of the right lung. The blood culture was sterile.

Treatment and Course.—On admission the patient received 4 Gm. of sulfadiazine and then 1 Gm. every four hours. The following day the patient appeared moribund, being semistuporous and extremely dyspneic and cyanotic. In addition to the pneumonia there were signs of severe congestive heart failure and auricular fibrillation. The patient was therefore given stimulants, first 0.75 mg. of ouabain and then digitoxin. At the same time penicillin was substituted for sulfadiazine, the patient receiving 50,000 units every three hours. He was also placed

in an oxygen tent. There was a satisfactory clinical response, with improvement of the heart failure and reduction in the fever.

On the seventh day the temperature rose to 103 F., and there were signs of fluid at the base of the right lung. The sputum now showed untyped pneumococci, staphylococci and gram-negative bacilli.

On the eighth day a thoracentesis yielded 900 cc. of sero-sanguinous fluid which showed gram-positive diplococci that did not type with pneumococcus II serum. One hundred thousand units of penicillin were injected intrapleurally. At the same time the intramuscular dose was increased to 200,000 units every three hours. From the eighth to the twenty-first day the patient had a septic temperature. Roentgenograms taken on the fourteenth day showed two fluid pockets. The aspirations of the chest were repeated and were followed by the intrapleural instillation of penicillin, resulting in sterilization of the empyema pockets.

On the eleventh day, the gram-positive cocci in the sputum culture were overgrown by the gram-negative bacilli, and on the fourteenth day there were only gram-negative bacilli, identified as *E. coli* and *A. aerogenes*. The *E. coli* was sensitive to 1.53 and the *A. aerogenes* to 0.38 unit per cubic centimeter of streptomycin.

Since there was no improvement and in view of the presence of the gram-negative bacilli, the penicillin therapy was stopped and streptomycin therapy was begun on the sixteenth day, with a daily intramuscular dose of 3 Gm. At that time it was thought that the pulmonary parenchyma was breaking down, resulting in the expectoration of large amounts of thick yellow nonfoul sputum.

On the twentieth day the sputum culture failed to show the gram-negative bacilli and again showed gram-positive cocci. Accordingly, combined penicillin and streptomycin aerosol therapy was instituted, 50,000 units of each, for eight treatments daily. This resulted in prompt and progressive improvement. There was a drop in temperature and diminution in the expectoration. The patient's convalescence was uneventful and his recovery complete.

COMMENT

In these 2 cases of pneumococcal pneumonia there developed during the course of penicillin therapy new infections due to organisms not susceptible to this antibiotic. Summaries of the data in these 2 cases are shown in figures 1 and 2. In case 1 a course of penicillin therapy resulted in clinical improvement, with the disappearance of the pneumococci from the blood and sputum. This was followed by the emergence of gram-negative bacilli, identified as *E. coli* and *A. aerogenes*, and the simultaneous aggravation of the clinical picture, requiring the use of streptomycin. The pneumonia in case 2 was complicated by congestive heart failure and empyema. After the administration of penicillin intramuscularly and intrapleurally the gram-positive organisms disappeared from the sputum and pleural fluid. However, there occurred a new infection due to *E. coli* and *A. aerogenes*. The institution of streptomycin therapy led to clinical improvement and the disappearance of the gram-negative pathogens. It may be of interest to note that in both cases during the administration of streptomycin the gram-positive cocci returned, necessitating supplementation with penicillin.

As Weinstein^{2a} has pointed out, the mechanism by which the new infection occurs is not clear, but may be due to a disturbance in the degree of bacterial antagonism, which is normally present. It is possible that the removal of bacteria with a specific antibiotic causes insensitive organisms to increase not only in number but also in virulence.

The occurrence of superinfections in patients receiving penicillin or streptomycin serves to emphasize the importance of frequent and careful bacteriologic examinations before and during the course of treatment. The highly specific qualities of antibiotic agents neces-

sitate the accurate identification of causative organisms whenever they arise.

It has been suggested that the combined use of penicillin and streptomycin may prevent the occurrence of superinfections. Since the incidence of new infections does not appear to be high, the routine use of combined therapy is, to our minds, unwarranted. There is also an objection that treatment with both drugs may sensitize certain patients to their use later in life. It therefore seems best to watch for new infections and to use each antibiotic in a specific manner, depending on the precise bacteriologic observations at a given stage of the disease.

SUMMARY AND CONCLUSIONS

Two cases of pneumococcic pneumonia, in which following penicillin therapy there developed a new infection due to gram-negative bacilli, are described.

We have stressed the importance of frequent and careful bacteriologic examinations in all patients before and during treatment with an antibiotic, in order to detect the presence of superinfections.

The treatment of infections from the start with a combination of penicillin and streptomycin is not advisable.

PREGNANCY TEST USING THE MALE BATRACHIA

CARLOS GALLI-MAININI, M.D.
Buenos Aires, Argentina

In March 1947 I¹ published the first results of a new biologic pregnancy test, in which male toads, "*Bufo arenarum* Hensel," were used as the reacting animals.

One year has elapsed since the first experiments were made, in January 1947, and it is believed useful and desirable to summarize the information obtained since then from the accumulated statistics and the many papers published on the subject.

The basis of this reaction is the phenomenon which occurs in the testicle of the adult male toad as a direct result of gonadotropic stimulation. The positivity or negativity of the reaction to the test is produced by the presence or absence of spermatozoa in a drop of toad's urine, collected by means of a pipet and observed microscopically within a few hours following the subcutaneous injection of 10 cc. of urine from the woman suspected to be pregnant.

ANATOMIC AND PHYSIOLOGIC CONSIDERATIONS

The testicle is a dual organ, of elongated form, located in the dorsal region of the celomic cavity, parallel to the spine and united by means of a short ligament to the corresponding kidney.

The general structure is similar to that of the testicles of superior animals. It has seminiferous ampules or tubes, interstitial cells and supporting tissue.

Collecting tubes depart from the seminiferous ampules, go through the ligament, get into the kidney and end in certain glomeruli.

This anatomic distribution indicates that the routes of excretion, starting from the kidney, are common to the spermatozoa and to the urine.

The spermatogenesis of the *Bufo arenarum* Hensel develops in round cellular conglomerates, called sper-

matocytes or follicles. The spermatozoa derived from each spermatocyst remain attached to the Sertoli cells, grouped together and parallel to each other in such a way that they appear like bundles. Only occasionally the spermatozoa are free and detached from the wall of the tubes and can be seen as a loose skein. The study of the sexual system of the male toad, "*Bufo arenarum* Hensel," and the relation between the hypophysis and the testicle was started in 1923 by Giusti and Houssay² and continued by several authors.³

Houssay and Lascano González^{3c} said:

It is evident that in the toad the hypophysis has a constant influence on the spermatogenetic testicular activity. . . . The removal of the hypophysis produces testicular atrophy in the toad. . . . The repeated subcutaneous implantation of toad's hypophysis produces testicular hypertrophy in normal and hypophysectomized animals.

Gonadotropic administration stimulates the interstitial cells and the spermatogenesis and acts on the Sertoli cells.

The spermatozoa produced in the ampules are detached from the Sertoli cells by the gonadotropic action, a phenomenon studied in detail by de Robertis, Burgos and Breyter in 1945 and 1946.⁴ Once they are free, following the excretion tubes, the spermatozoa go through the corresponding glomeruli and down the ureter to the bladder and are excreted subsequently with the urine. These batrachia reproduce by external fecundation. During the sexual period, the end of the winter and beginning of spring for the *Bufo arenarum* Hensel, the toads seek small pools or calm waters, and the male toad rides and embraces the female toad. This embrace, or amplexus, is a tonic reflex difficult to overcome, lasts several days and starts a series of nervous and humoral phenomena, among which the discharge of pituitary gonadotropins is the most important. Under the effect of its own gonadotropins, the female toad ovulates and expels the ovules to the exterior in transparent threads of a gelatinous substance produced by the oviduct. In the male toad, the spermatozoa detached by the gonadotropic action are expelled with the urine and fertilize the ovules contained in the ovular threads.

MATERIAL AND METHODS

Batrachia Used.—Up to the time of writing the following batrachia have been used: the *Bufo arenarum* Hensel,⁵ *Bufo*

paracnemis,⁶ *Bufo marinus* and *Bufo crucifer*,⁷ *Calyptocephallus gayi*,⁸ *Leptodactylus ocellatus*,⁹ *Xenopus laevis*,^{7b} *Odontophrynus*,^{7b} *Rana pipiens*¹⁰ and, lately, *Bufo d'Orbigny* (by me). It should be noted, however, that the possibility of seasonal variation is not known for the *Rana pipiens*. Seasonal unresponsiveness can be observed in some batrachia with "cyclic spermatogenesis," in which spermatozoa are produced only during a certain period, the testicle being at rest between the active seasons. Because of this reason the selection of a batrachia with "continuous spermatogenesis" will provide a reliable test animal throughout the year.

It is interesting to note that Robbins, Parker and Bianco¹¹ have obtained positive results injecting pituitary and chorionic gonadotropin in the male *Xenopus laevis*.

These authors did not state whether they have experimented with pregnant woman's urine and suggested the future use of this animal as reactive for pregnancy.

The batrachia must be male and adult. The sexual characteristics of the male toad are: its size, smaller than that of the female toad, its uniform green color, stronger forearms, dark brownish pigmentation in the inward border of the "thumb"; it "croaks" when taken between two fingers and has the sexual reflex of the amplexus. These characteristics are absent in the female toad.

Weight: The weight of the animal must not be less than 100 Gm. if the *Bufo arenarum* Hensel is used or 25 to 30 Gm. if the *Bufo d'orbigny* is used. The *Bufo paracnemis* Lutz should weigh between 100 to 350 Gm.^{6a}

Captivity: These batrachia are easily captured in large gardens and in the open spaces with vegetation and humidity and are maintained in containers of varied sizes, according to the necessities of the laboratory. Basins of 1 meter by 60 cm. by 60 cm. are used in the laboratory of the Rivadavia Hospital, which allows keeping simultaneously and comfortably about 300 animals in each.

While in captivity, the only requirement of the animals is that the place which they inhabit be kept damp. If basins are used, the dripping of a faucet is sufficient. The place should be humid, but immersion of the animals in the water should be avoided, even partially, as in those conditions they die within two or three days. Moderate temperature is preferable. Excessively low temperatures, such as 4 and 5 C. (39 and 41 F.), retard (but do not inhibit) the reaction. During the time of captivity, which may be of several months, they are not given any food. During this period they live on their reserves and can be used repeatedly.

Collection and Injection of the Patient's Urine.—The specimen of the woman's urine can be that of any time of the day, though that of the first miction of the morning is customarily used. This specimen is placed in a clean nonsterile bottle. The patient from whom the urine is to be obtained does not need to have any special diet the previous day, nor need she deprive herself of any medication. The urine is injected directly in the toad, without filtration, concentration, adjustment of pH or any other previous preparation.

Ten cubic centimeters are injected subcutaneously, either in the dorsum or the abdomen, according to the authors. In the batrachia, the skin adheres to the body only in reduced zones, as the middle of the spine and the ventral line, the head and the joints. In the remaining parts the skin is separated from the body, forming great gaps or sacs, through which the lymph circulates. It is for these reasons that, in spite of being proportionally of great volume, 10 cc. of urine can be injected, since it quickly spreads in these lymphatic sacs.

Procurement of Urine Samples from the Batrachia.—The animal is held dorsally against the table, and a pipet is introduced in the "cloaca," to a depth of about 0.5 cm., and is

gently moved back and forth until a drop of urine is seen to penetrate the pipet.

Microscopic Observation.—The drop of urine thus obtained is placed on a slide and observed directly under the microscope without previous smearing, fixing or staining. Strong illumination should be avoided. In these conditions a positive result is revealed by the presence of many spermatozoa occupying the microscope's field and appearing in great quantities as delicate undulating short dark lines. The mobility of the spermatozoa is of no importance for the interpretation of the result, since what counts is their presence. It is important not to confuse the small scratches that the slides may have and not to illuminate the microscope excessively or to make the observation at great enlargement. In some cases the lack of contrast of the preparation may make the spermatozoa pass unnoticed.

Time of Observation.—Up to the date of writing, 89 per cent of the positive results obtained by me were obtained within two hours of the injection of pregnant woman's urine. According to Blanchard,^{6a} 96 per cent occur within an hour and a half. Sala and his co-workers^{5b} observed that 84.5 per cent occur in an hour and 100 per cent three hours after the injection. For absolute certainty it is convenient to extend observation of the negative reactions until twenty-four hours have passed, if the test is made at low temperatures.

Repetition of the Test in the Same Animal.—There may be an interval of one week between one test and another. Each animal can be used generally four or six times.

Reaction During the Time of Reproduction of the Batrachia.—The period of reproduction of the batrachia is not an obstacle for the realization of the reaction. At this time, spontaneous elimination of spermatozoa has never been observed in the toads which are not embraced. During the sexual period the spermatozoa detach and migrate to the toad's bladder only under gonadotropic stimulation, which is due to the discharge of their pituitary gonadotropins as a consequence of the amplexus.

For greater security, however, the toads captured during amplexus should not be used immediately, and it is convenient to observe microscopically the urine of all the toads before performing the test, to be certain of the negativity of the reaction.

Routine and Practice of the Test in the Laboratory of Rivadavia Hospital.—The toads are brought in quantities, calculated as necessary, approximately for two hundred tests a month, and placed in three basins. Each specimen of urine is injected into 2 toads. The toads kept in the different basins are used alternately in such a way that a minimum of a week elapses before the same animals are used again. When all the toads have been used four or six times, they are discarded and replaced with new ones.

The injection is made subcutaneously, with a syringe of 10 cc. and a large needle. The skin of the middle dorsal line is pierced, and the needle is introduced up to the point where it is noticed under the skin of the lymphatic lateral sac, and the urine is injected. The injections and observations are made during the morning hours. The toads which react negatively the same morning that the injection is given are kept under observation in order that they may be observed again the following day. For each observation the same pipet and the same slide are used; they are washed carefully under water between each reading.

To permit differentiation of the pairs of toads receiving the different specimens of urine, they are kept in small numbered cages or are marked by different colored threads tied on the legs or arms.

After the injection is given, the toads are kept at the natural temperature and illumination of the laboratory.

RESULTS

In all, 2,030 tests have been performed by me, the reactions to which are interpreted as follows: suspected pregnancy up to the fifth month of amenorrhea in 1,896 cases, pregnancies from the sixth to the ninth

6. (a) Mayer, H. F.; Govi, L., and Flores, J. F.: Read before the conference at the Colegio nacional Gral. S. Martin, Corrientes, Oct. 18, 1947. (b) Caldeira Algodoal, F.: Personal communication to the author.

10. Wilterberger, P. B., and Miller, D. F.: Science 107: 198, 1948.

11. Robbins, S. L.; Parker, F., Jr., and Bianco, P. D.: Endocrinology 40: 227, 1947.

month in 123 cases, suspected ectopic pregnancies in 7 cases, chorioepithelioma in 2 cases and mole in 2 cases.

Positive or Negative Verified Results.—The accuracy of the result could be verified in 1,422 cases of suspected pregnancy; in 960 instances the patient was not pregnant and negative results were obtained in all. In 462 cases of verified pregnancy, positive results were obtained in 458, i. e., a rate of accuracy of 99.01 per cent. All told, in 1,422 tests, there were errors in 4 cases, a rate of accuracy of 99.72 per cent.

Other authors obtained correct results in 98 per cent to 100 per cent of the tests: 100 per cent in 82 cases of pregnancy of less than five months,^{5c} 99 per cent in 100 cases of pregnancy,^{5d} 99.20 per cent in 103 cases of pregnancy up to the fifth month and ^{5k} 98 per cent in 50 cases ^{5h} (these authors obtained 1 erroneous result, but the reading was made two and a half hours after the injection was given), 98 per cent in one hundred tests in verified pregnancies,^{5l} 100 per cent in 69 cases of pregnancy of less than six months,^{5o} 100 per cent in 300 tests ⁵ⁱ and 98.19 per cent in 165 cases of pregnancy of less than four months.^{5m}

Toxicity of the Reaction.—Of the toads used in 2,030 tests, 23 toads died because of the injection, a mortality rate of 1.13 per cent. Comparatively, in 326 Friedman tests, 14 pairs of rabbits died, that is, 4.37 per cent.

Blanchard and Bretto ^{5k} noted a mortality rate of 1.5 per cent and Figueroa Casas and his co-workers ^{5e} 0 per cent in 150 tests.

Comparative Results with the Friedman Test.—In 326 Friedman tests, 14 pairs of rabbits died. Of the remaining 312 tests, made simultaneously in the toad and the rabbit, 291 gave coincident results. Of the noncoincident results in the 21 cases, in 17 cases the result obtained in the toad was correct and in 2 cases incorrect. In the remaining 2 cases, the results could not be verified.

Speed of the Reaction.—In 522 cases in which the results were positive the reactions were observed at intervals of one, two and twenty-four hours after the injection was given. Of these, reactions were positive in 254 cases at one hour, in 212 at two hours and in 56 within the twenty-four hours. In 3 cases the result was positive in thirty-five minutes. The data obtained indicates that 89 per cent of the positive reactions occur within the first two hours after the injection is given. It is probable that if the results had been observed three hours after the injection was given the majority would have been positive.

Blanchard and Bretto ^{5k} observed that 96 per cent of the positive results were obtained one and a half hours after the injection was given; Sala and his co-workers ^{5h} noted 100 per cent positive results after three hours and 84.5 per cent within the first hour.

Specificity of the Reaction of the Toad to the Injection of Urine.—The injection of 623 specimens of urine of nonpregnant subjects, men, women and children, who were normal or had a variety of pathologic conditions, gave constantly negative results. The results of the administration of other hormones or substances are described further on.

Five hundred and forty-three control tests—which represent the statistics accumulated from other authors ¹²—were made with urine of nonpregnant persons, and in all the cases the result was negative, that is, an accuracy of 100 per cent.

Precocity of the Reaction.—Positive results have been obtained with specimens of urine from pregnant women with as little as four (1 case) and five (2 cases) days of amenorrhea.¹³

Results Obtained with Urine and Serum in Pregnancies Between the Sixth and Ninth Month.—Tests with Urine: Eighty-four tests were made, the reactions to six of which were negative, that is, 92 per cent gave positive results, of which 84 per cent occurred within the two hours after the injection was given.

Tests with Serum: Thirty-nine tests were performed injecting varied quantities of serum (between 3 and 7 cc.), and it was observed that the serum of women in the sixth to the ninth month of pregnancy gave 69 per cent positive reactions, 54 per cent of which occurred within two hours after the injection was made. No relation has been observed between the quantity of injected serum and the result obtained.

Other authors have also observed a lower incidence of positive reactions in pregnancies between the sixth and the ninth month.

Results in Suspected Ectopic Pregnancies.—Of test performed in 7 cases, there were positive correct reactions in 2, in 1 of them in forty-five minutes and another one hour after the injection was given. In the remaining 5 cases, results were verified as negative. The experience of other authors are coincident.

Chorioepithelioma...	..	..	..	..	..	1

Chorioepithelioma and Mole.—The reaction was positive in 2 cases of chorioepithelioma and in 2 of hydatiform mole. On the other hand, Pinto and Suer Boero ^{5f} obtained negative results in 1 case of chorioepithelioma.

Quantitative Reactions with Urine of Pregnant Women.—The quantitative determinations were performed as follows:

Increasing dilutions were made with each specimen in such a manner that each one of them contained 4, 2, 1, 0.5, 0.25 and 0.125 cc. of the urine in a total volume of 8 cc. With each one of these dilutions, 2 toads were given injections—12 in total—twenty-four hours after the minimum quantity of urine which produced positive reaction was established.

In order to make approximate comparative estimation of the content of international units of chorionic gonadotropin per liter of urine, it was assumed, on the basis of experiments the results of which are described further on, that approximately 40 international units of chorionic gonadotropin per toad are needed to obtain positive results. Sixty quantitative determinations were performed: in 17 cases with urine of women pregnant less than one month, in 31 cases from one to three and a half months, in 11 cases with specimens of urine of women pregnant more than three months and in 1 case of chorioepithelioma. The results obtained are seen in the table. It is interesting to note that a larger number of positive results were obtained in pregnancies of one to three and a half months of evolution, in which

¹²12. Footnote 5d-m. Mayer, Govi and Flores.⁶

13. Galli-Mainini.¹ Footnote 5a-m. Mayer, Govi and Flores.⁹

period 4 pairs of toads gave positive results with 0.125 cc. of urine; the specimens of urine contained roughly the equivalent of 320,000 international units of chorionic gonadotropin per liter, a quantity equal to that estimated in the case of chorioepithelioma.

Experiments not published yet show that *Bufo d'Orbigny* is more sensitive than *Bufo arenarum* Hensel, since positive reactions are obtained with this animal by injecting 0.015 cc. of urine. This animal, due to his greater sensitivity, is probably the most adequate for quantitative determinations.

Duration of the Gonadotropic Activity of Urine.—Quantitative determinations were performed daily, according to the described technic, and it was observed that the specimens of urine keep a great part of their gonadotropic activity even ten days after their emission, when they are kept at room temperature or at 4 C. (39.2 F.). For instance, positive results were obtained the first day with 1 cc. of a specimen of urine and ten days later with 2 cc. of the same specimen.

The same observation was made by Gori,¹⁴ who noted gonadotropic activity in 8 specimens of urine after they had remained at room temperature for seven days.

Conditions and Factors Related to the Gonadotropic Action in the Male Batrachia.—Some of the factors related to the test have been experimentally studied by me.¹⁴ Houssay¹⁵ and Pinto and me.¹⁶ The complete data on these experiments have been published elsewhere and are not reported here.

Specificity of the Reaction.—Positive Results: Up to the date of writing, positive results have been obtained with chorionic, serous and pituitary gonadotropins, with a follicle-stimulating hormone preparation from bovine pituitary gland (Dr. Mendive) and with crude suspension or implantation of pituitaries from the rat, rabbit and other batrachia.¹⁰

Chorionic gonadotropins produced positive results in male toads after removal of the brain, lungs, gastrointestinal tract, pancreas, spleen and pituitary gland.¹⁰ Pinto and I¹⁶ observed positive reactions following the injection of chorionic gonadotropin, or pregnancy urine, even seventy-eight days after the pituitarectomy.

It has been observed¹⁰ that the hepatectomy enhances the capacity of the toad to react to smaller doses of chorionic gonadotropin.

Destruction of the medulla, unilateral castration and anesthesia do not abolish the reaction to the administration of chorionic gonadotropin and pregnancy urine.¹⁷

Experiments were performed in vitro by Burgos and Mancini,¹⁸ and they observed, on histologic study, free spermatozoa when the medium contained chorionic or serous gonadotropin or crude suspension of toad pituitary.

Negative Results: Consistently negative results followed the injection of 623 specimens of urine from nonpregnant women, men and children, who were in normal health or who had a variety of pathologic conditions. The same results were attained by others with a total of 543 control specimens of urine.¹²

The injection of concentrated or unconcentrated urine from women in menopause or castrated women gave negative results.¹⁰

No response was observed to the injection of different doses of estradiol benzoate, progesterone, testosterone

propionate, desoxycorticosterone, "pitressin" N. N. R., thyroxin, adrenalin and prolactin.¹⁰ These observations were confirmed by Houssay,¹⁵ who also noted negative results following the injection of adrenocorticotropin, corticotropin, pituitary gland from cattle, dog, swine, guinea pig, cat and *Grotalus terrificus*, urine from pregnant rat, ascorbic acid, crude suspension of liver, kidney, adrenals, spleen, heart, muscle, gastrointestinal tract and pituitary intermediate lobe from *Bufo arenarum* Hensel. Negative results were obtained injecting methylene, zinc sulfate and serum from pregnant cow.²⁰ This last result was also obtained by Mayer, Govi and Flores,⁹ in addition to negative responses after injection of urine and serum from pregnant mare and swine.

Minimal Necessary Doses of Gonadotropin.—I¹⁰ studied the response of the toad to different amounts of chorionic gonadotropin. Two hundred and fourteen toads, kept at 15 to 18 C. (59 to 64 F.), received 1, 10, 20, 30, 40, 50, 100, 500, 1,000 and 1,500 international units by injection, and it was noted that 40 international units produced 90 per cent positive results, while with 30 international units only 18 per cent positive responses were obtained. From this experiment it is assumed that the minimal necessary dose is grossly 40 international units of chorionic gonadotropin, if given by injection to a normal toad. This quantity is reduced to 10 international units if hepatectomized toads are used. In 54 such animals, the injection of 10 units gave 82 per cent positive results. When serous gonadotropin is injected, higher doses are necessary to obtain positive results.

Route of Administration.—The intracardiac injection on small doses of chorionic gonadotropin was observed to be more effective than the subcutaneous, intramuscular or intraperitoneal injection. No effect followed the administration of 100 international units, or 10 cc., of pregnant urine by gastric route.

Effect of the Temperature.—Temperature is a modifying factor on the response of the toad to the administration of gonadotropin. It has been observed²⁰ that low temperatures, as 4 or 5 C. (39 or 41 F.), will inhibit the response only when minimal doses are injected. With pregnancy urine or higher doses of chorionic gonadotropin, positive responses are delayed but not inhibited.

Speed of the Reaction.—Spermatozoa are usually observed in the ureter of the toad within ten minutes following the injection of large doses of chorionic gonadotropin and can be obtained from the bladder within twenty to sixty minutes. The reaction takes place more slowly when serous gonadotropin is injected.²¹

Effect of Illumination.—Forty toads were exposed to the light for twenty-four hours and inoculated with small doses of chorionic gonadotropin, and the results compared with those obtained in 40 toads kept in total darkness for the same length of time and treated in similar manner. The results show that these last toads reacted to smaller doses and for a longer time than the ones exposed to the light. However, illumination is not a factor to be taken into consideration when pregnancy urine is injected, as identical results are obtained with toads exposed to the light or kept in darkness. This fact is probably due to the high gonadotropic titer of pregnancy urine.

COMMENT

Previous studies, the result of the pregnancy test and the physiologic experiments indicate that the gonadotropic stimulation in the male batrachia has a direct effect on the testicle, where its targets are the interstitial cells, the spermatogenesis and the Sertoli cells. The reaction develops quickly; it is specific for some gonadotropins, and the response is slightly different when chorionic, serous or pituitary gonadotropins are injected.

An interesting fact is the quick response of the Sertoli cells to gonadotropins. Practically, it can be said that the presence of spermatozoa in the batrachian urine is indirect proof that the injected substance has acted on these cells.

This phenomenon, the characteristics of the batrachia as sturdy experimental animals and the speed, simplicity and net end point of the gonadotropic effect, indicate that the male batrachia are useful reacting animals and opens a new field for interesting investigations.

The data of the pregnancy reaction suggest that this new biologic test possesses advantages when compared with the present usual tests.

Specificity.—When urine was injected, positive reactions have been obtained exclusively with urine from pregnant women or with chorioepithelioma or hydatiform mole. The fact that in 1,166 cases control tests gave 100 per cent correct results indicates that, up to the date of reporting, a false positive result never occurred. On the other hand, pregnancy tests were performed in 2,661 cases in all, and results obtained were correct in 98 to 100 per cent.

Speed of the Reaction.—A high percentage of the results can be obtained within three hours following the injection of urine. The present percentage is 89 per cent within two hours according to my studies, 96 per cent positive results and one and a half hours according to Blanchard and Bretto²² and 100 per cent three hours after the injection of urine according to Sala and his co-workers.²³

Simplicity of the Technic.—The performance of the test is simple because: (a) No special preparation of the urine to be injected is needed; (b) the injection is without difficulties; (c) the collection of the toad's urine is simple, and no surgical intervention is needed; (d) the microscopic observation is immediate, without previous histologic procedures; (e) the microscopic differentiation of spermatozoa is simple because of their number and well defined characteristics of structure and movement, and (f) the several steps of the technic can be performed rapidly—usually one observation will not take more than one minute from the moment that the toad is taken from the cage until the result is established.

Clear End Point.—The positivity of the reaction is clearly indicated by the presence of spermatozoa in the toad's urine. Spermatozoa are absent in urine of toads which did not receive injections or received injections with urine of nonpregnant subjects.

Economy.—The economy of the procedure is due not only to the low cost of the toad but also to the fact that no special care is needed, i. e., in matters such as food, handling and personnel. In addition, the same toad can be used again after an interval of one week.

CONCLUSIONS

1. Studies made on the male toad indicate that it is a good reacting animal to gonadotropins.

2. Gonadotropic administration stimulates the interstitial cells and the spermatogenesis and produces detachment of spermatozoa from the Sertoli cells. Free spermatozoa migrate to the bladder and can be obtained by means of a pipet introduced into the cloaca.

3. Up to the time of reporting, this response has been provoked with chorionic, serous and pituitary gonadotropins and with crude suspensions of pituitary gland from other batrachia, the rat and the rabbit.

4. The reaction of the testicles to gonadotropic stimulation is, to some extent, influenced by the dose, the route of administration, the temperature and the illumination.

5. The phenomenon of detachment and migration of spermatozoa has practical application in the diagnosis of pregnancy by means of a new test used on the male batrachia. The presence of spermatozoa in a drop of toad's urine a few hours after the injection of 10 cc. of urine from a pregnant woman indicates a positive result.

6. Results seem to be specific for urine of pregnant women because negative results are constantly obtained when urine from nonpregnant subjects is used.

7. In 2,661 cases, tests made with urine of women suspected to be pregnant yielded correct results in 98 to 100 per cent.

8. A modified technic of this test has proved to be useful for quantitative gonadotropic determinations.

9. This reaction has the advantages of specificity, speed, simplicity, clear end point and economy.

SUMMARY

Results obtained with a new test for the diagnosis of pregnancy in which normal male batrachia are used are reported. A positive result is indicated by the presence of spermatozoa in the animal's urine after the injection of 10 cc. of urine from pregnant women. Accumulated data show 98 to 100 per cent correct results in pregnancy tests in 2,661 cases and 100 per cent exact negative response in 1,166 cases in which control tests were made with urine from nonpregnant subjects. Quantitative aspects were studied as well as the influence of such factors as illumination, temperature, dose of chorionic gonadotropin, method of injection, gonadotropin of different species, total hepatectomy and injection of hormones and substances.

This pregnancy test has the advantages of specificity, simplicity, speed of the reaction, clear end point and economy.

Lafinur 3339, Buenos Aires, Argentina.

We Need to Be Humble.—In all aspects of medicine we need to be humble. We can be proud of what has been accomplished . . . so long as it does not blind us to the fact that most progress has occurred in relation to acute diseases. Despite great advances in the control of bacterial diseases, and however great such advances may be in the future, medical science must always go forward. It is remarkable . . . that no sooner is the cure or control of one disease accomplished than new problems appear to arise. . . . At one time it seemed that gonorrhea could be almost controlled with the sulphonamides, but nowadays it is recognized that a large proportion of cases, many more than hitherto, are sulphonamide-resistant. Is this an example of the aphorism "Make haste to use a new remedy before it is too late," or is it that bacteria are really capable of rapid adaptation? The latter is probably the truth. In due course penicillin-resistant staphylococci may become common, whereupon the whole search must begin again. Likewise with streptomycin, to which resistance appears to be quickly established.—Sir Lionel Whitby, M.D., *British Medical Journal*, July 3, 1948.

Clinical Notes, Suggestions and New Instruments

OUR NATIONAL PARKS AS RAGWEED HAY FEVER REFUGES

OREN C. DURHAM, Ph.D.
North Chicago, Ill.

The accompanying tabular data on the ragweed pollen hazards in the national parks were secured over a period of thirteen years, during which I made field studies and carried out routine atmospheric pollen tests for one or more seasons in each of the parks and areas herein listed, except as noted. Most of the atmospheric tests have been made by the standard technic recommended by the Aero-Allergen Council of the American

From the Abbott Laboratories, North Chicago, Ill.

The field and atmospheric surveys in this series were made possible by the following organizations: American Academy of Allergy, Abbott Laboratories, Curtis Publishing Company, Glacier Park Hotel Company, Glacier Park Transport Company, Grand Canyon-Boulder Dam Tours, Inc., Great Northern Railway, Mesa Verde Company, United Air Lines, United States Department of the Interior (National Park Service), United States Weather Bureau, Utah Parks Company (Union Pacific Railroad), Western Air Express, Yellowstone Park Company and Yosemite Park and Curry Company.

Academy of Allergy.¹ The figures for "days of high incidence" refer to the average number of days per season when the ragweed pollen concentration reached or exceeded 25 pollen granules per cubic yard of air. "Maximum atmospheric concentration" refers to the highest number of ragweed pollen granules per cubic yard of air during any one twenty-four hour period. A "seasonal total" is the cumulative figure obtained by adding the number of ragweed pollen granules per cubic yard for each day throughout the season. The "index" figure is an arbitrary rating based on the three factors: average length of season, maximum concentration and average seasonal total.² Areas with an index rating of 10 or more cannot be recommended as suitable for those seeking relief from ragweed hay fever. Preference should be given to parks with indexes less than 5. These may be rated from "fair" to "good." Those areas with indexes less than 1 are excellent ragweed refuges unless heavily infested with sagebrush. It will be noted that the parks of the Rocky Mountain, Cascade, Olympic and Sierra regions are almost entirely free from airborne ragweed pollen.

SUDDEN DEATH FOLLOWING INTRAVENOUS
ADMINISTRATION OF "DIODRAST"SAMUEL SIMON, M.D.
Poughkeepsie, N. Y.

The basis for this report is a fatality subsequent to the intravenous administration of iodopyracet injection ("diodrast"). The incidence of such fatalities is rare. Pendergrass and his co-workers,¹ in 1942, following a fatal reaction to iodopyracet injection at the University of Pennsylvania, made a survey of this diagnostic procedure throughout the United States and Canada. They sent out three thousand questionnaires to radiologists and urologists and received a report on 661,800 urographic examinations. In analyzing these reports, they encountered twenty-six unreported fatal reactions to iodopyracet injection in addition to eleven fatalities that had been reported in the literature up to that time. This represented an incidence of one fatality to twenty-five thousand injections. They reported two types of deaths: (1) immediate, due to allergy to the drug, and (2) delayed, due to preexisting major renal damage. Eleven of twenty-six deaths were immediate deaths, occurring in an average time of thirty minutes subsequent to the injection. All of the immediate deaths were of patients who had received iodopyracet injection. None of the patients who died had been subjected to the recently proposed tests for sensitivity to the drug. Pendergrass stated that no immediate deaths had been reported following retrograde pyelography with any contrast mediums.

Deaths following the intravenous administration of iodopyracet injection have also been reported by Crane,² Cumming and Chittenden,³ Dolan⁴ and Goldburgh and Baer.⁵

REPORT OF A CASE

C. F. a 23 year old white man was admitted to the 189th General Hospital in Mourmelon, France, on Oct. 2, 1945, with the chief complaint of blood-tinged urine of three days' duration. The patient stated that he had been involved in an automobile accident three days prior to admission and had

sustained injury at the time to the left upper quadrant of the abdomen and the lower left anterior costal margin. Subsequent to the accident, the patient had noted blood-tinged urine. There were no other urinary symptoms.

Past history revealed that the patient's general health had been good. There was no history of any previous allergic manifestations. There was no history of any previous serious illnesses or operations.

Physical examination revealed a well developed well nourished 23 year old white man who did not appear acutely or chronically ill. He was alert, cooperative and ambulatory. His blood pressure was 140 systolic and 90 diastolic. The heart and lungs were normal. Examination of the thorax revealed moderate tenderness over the left lower ribs anteriorly. Examination of the abdomen revealed no tenderness or rigidity. No masses were noted. There was no costovertebral angle tenderness. The kidneys and spleen were not palpable. The genitalia were normal. Results of the rectal examination were negative.

Laboratory studies revealed that the urine was grossly clear at the time of admission, with a specific gravity of 1.020, no sugar and no albumin. Microscopic examination revealed 10 to 15 red blood cells per high power field. The blood cell count was within normal limits. Blood urea nitrogen was 16 mg. per hundred cubic centimeters.

The clinical impression at the time was that the patient had a contusion of the left lower costal region anteriorly. The possibility of injury to the left kidney was also considered, and an intravenous pyelogram was ordered.

On October 3, the patient was referred to the x-ray department for an excretory pyelogram. Twenty-five cubic centimeters of a 35 per cent sterile aqueous solution of iodopyracet injection was administered intravenously. The drug was given slowly over a period of five minutes. The injection itself was completed without incident. Approximately three minutes after the injection, however, the patient suddenly began to vomit, and he stated that he felt "numb all over." One cubic centimeter of epinephrine was given immediately. The patient at the time evidenced a rapid thready pulse and decided cyanosis. The patient was returned to the ward, and oxygen was administered. Despite all supportive measures, which consisted of administration of oxygen, epinephrine and nikethamide, the patient's cyanosis became more apparent and his respirations became very irregular. The degree of shock increased, and the patient died twenty minutes subsequent to the iodopyracet injection. Clinical impression at the time was that death was an allergic reaction due to iodopyracet injection.

An autopsy was performed the same day by Dr. S. Sjöback, with the following observations. There was decided congestion and edema of all the viscera. The lungs revealed scattered subpleural petechial hemorrhages over all the surfaces. The

heart was normal. The gastrointestinal tract revealed internal cyanosis of the mucosa. The brain also revealed many small petechial hemorrhages throughout the white matter.

COMMENT

On the basis of the postmortem observations presented in this case, it was felt that this fatality was allergic in origin. Allergic manifestations to iodine are not rare. This fact must be constantly kept in mind with the administration of iodopyracet injection. In order to forestall such reactions, I have adopted the following precautions in administration:

1. The patient is questioned carefully with regard to any previous history of allergic manifestations: asthma, hay fever, hives, rose colds, excessive sneezing, excessive headaches, headaches due to drugs, previous iodine medication and previous excretory pyelography. The patient should also be questioned with regard to any family history of allergy.

2. A cutaneous test is performed, employing 0.05 cc. of undiluted iodopyracet injection intradermally. Naterman and Robbins⁶ reported 404 patients whom they tested in this manner, following this with an intravenous pyelogram. On the basis of their study, they expressed the belief that if the reaction to an intradermal test is strongly positive, with a wheal larger than approximately 15 mm., a serious general reaction may be expected. In those cases in which a local reaction to an intradermal test does occur, reaction occurs quickly following the injection and reaches a maximum in ten to fifteen minutes.

3. An oral test with undiluted iodopyracet injection is also performed. One to two cubic centimeters of the medium is placed under the patient's tongue and retained there for ten minutes, and then the patient is instructed to swallow. If the patient is sensitive to the drug, within a few minutes numbness about the face, swollen tongue and respiratory difficulty may develop. Dolan³ expressed preference for the oral rather than the cutaneous test. It has been my practice not to perform an intravenous pyelography if there is a definite history of allergy or if intradermal or oral tests elicit a positive reaction.

4. The drug is administered slowly; 1 cc. of contrast medium is injected intravenously, and then two minutes are permitted to elapse, during which period the patient is observed carefully. If there is no undue reaction, the remainder of the drug is administered slowly over a period of five minutes. Not infrequently, the patient may note a fleeting sensation of warmth. If the patient evidences any nausea, vomiting or respiratory difficulty, the injection had best be quickly discontinued.

5. An emergency tray is kept in the same room where the medium is being administered. This tray should contain: a 2 cc. syringe, hypodermic needles, a no. 19 gage needle, a tourniquet, an airway, an ampule file, a rubber-capped bottle of epinephrine (1 to 1,000), a rubber-capped bottle of atropine, ampules of caffeine sodium benzoate and calcium gluconate.

6. The patient should have either a nonprotein nitrogen or urea nitrogen determination prior to excretory pyelography. In the presence of decided renal impairment, evidenced by nitrogen retention, there is greater possibility of a reaction.

7. Patients with decided jaundice may be likely to have a reaction since some iodopyracet injection is eliminated by the liver.

8. Repeated urographic examinations may finally lead to a reaction.

Archer and Harris⁷ described ocular tests for determining sensitivity to iodopyracet injection prior to excretory pyelography. They employed an ocular test in 600 cases to determine sensitivity, and they observed this test to be more sensitive than either the oral or intradermal test.

Robb and Steinberg⁸ in 1939 reported interesting studies with iodopyracet injection as a contrast medium in the visualization of the chambers of the heart and the greater blood vessels. Their

studies would serve to indicate that iodopyracet injection was relatively nontoxic and inert. The relevant feature of their work is that they administered intravenously 25 to 45 cc. of a 70 per cent solution of iodopyracet injection in a period of two seconds. This dosage represents a range of 17.5 to 31.5 Gm. of iodopyracet injection in contrast to the 7 Gm. ordinarily employed for excretory pyelography. This large dose was injected extremely rapidly in this manner in 238 instances without fatality. In a recent communication, Dr. G. P. Robb stated that iodopyracet injection had now been administered in the aforementioned method for angiocardiology in over 800 cases. He reported that thus far there had been no fatalities and in only 5 or 6 cases was there a serious reaction. He stated further that he was regularly administering 1 cc. of a 70 per cent solution of iodopyracet injection intravenously to test for sensitivity.

SUMMARY

A case report of sudden death following the intravenous administration of iodopyracet injection ("diodrast") is presented. Precautionary measures in the use of iodopyracet injection are outlined.

94 Market Street.

Council on Foods and Nutrition

This paper was prepared at the request of the Council on Foods and Nutrition. JAMES R. WILSON, M.D., Secretary.

PASTEURIZATION AND ITS RELATION TO HEALTH

JOHN ANDREWS, M.P.H.

and

A. W. FUCHS, C.E.

Washington, D. C.

The importance of pasteurization in safeguarding milk supplies has been demonstrated conclusively over a long period of years. That raw milk can and does transmit disease and that pasteurization prevents such transmission has been proved to the satisfaction of health authorities by laboratory and commercial scale experimental work, by epidemiologic methods, by statistical methods and by animal experimentation.¹ More than five hundred and fifty American municipalities now require the pasteurization of all milk or of all except certified milk,² and action on a statewide basis recently has been taken by Utah, Michigan and Colorado.

REVIEW OF REPORTS

From time to time, however, the merits of pasteurization are challenged. One of the most recent attacks was embodied in a series of three articles in *The Rural New Yorker* and reprinted at the request of the Pennsylvania Raw Milk Producer-Distributors Association.³ As such attacks may do harm to the public health by tending to discourage the use of pasteurized milk, it is important that physicians be armed with the facts.

The literature is replete with accounts of outbreaks of milk-borne disease. Armstrong and Parran⁴ listed

Sanitary Engineer (R) (Mr. Andrews) and Sanitary Engineer Director (Mr. Fuchs), Milk and Food Section, United States Public Health Service.

seven hundred and ninety-one outbreaks of milk-borne disease in the United States as having been reported in the literature from Jan. 1, 1881, to Jan. 1, 1927. Beginning in 1923, the United States Public Health Service has made annual questionnaire surveys. For the twenty-three year period 1923-1945, state and local health authorities reported a total of nine hundred and fifty-five epidemics traced to milk and milk products, as shown in the table.⁵

Thus, during the period 1923-1945, there has been reported an annual average of forty-one outbreaks, involving 1,750 cases with 35 deaths. These data represent only a fraction of the actual amount of disease transmitted through milk and milk products. The reporting of outbreaks is probably far from complete, as is indicated by the fact that for 1938, for example, three states with only about one sixth of our population reported nearly as many outbreaks as all other states combined and that thirty-one states failed to report any outbreaks due to milk.⁶

The data given in the table do not include sporadic cases of such diseases as typhoid, scarlet fever and

Milk-Borne Disease Outbreaks Reported by State and Local Health Authorities as Having Occurred in the United States During the Years 1923-1945, Inclusive, by Disease

Disease	Outbreaks	No. of Cases	No. of Deaths
Typhoid	440	7,449	341
Scarlet fever and septic sore throat...	202	19,199	162
Food poisoning and gastroenteritis...	196	9,780	19
Brucellosis (undulant fever).....	34	275	3
Paratyphoid	27	1,063	22
Dysentery	20	1,413	20
Diphtheria	18	324	13
Miscellaneous	15	683	4
Total.....	953	40,177	504

septic sore throat, many of which may be milk borne. Furthermore, they do not include tuberculosis of bovine origin, infantile diarrhea nor any significant amount of brucellosis (undulant fever), all of which are largely milk borne but which usually occur as sporadic cases rather than in epidemic form. For 1945, about 5,049 cases of brucellosis and 101 deaths were reported in the United States. A considerable proportion of these cases, perhaps half, are believed to have been due to raw milk from infected animals. It is obvious that the actual amount of milk-borne disease is several times that indicated in the table.

The vast majority of the reported outbreaks of milk borne disease are due to raw milk and milk products. The reports received by the Public Health Service show that the risk of contracting disease from raw milk is approximately fifty times as great as from pasteurized milk (including milk which was only alleged to be "pasteurized milk").⁷

Pasteurization is the most important protective measure which can be applied to milk. Examination of cows and milk handlers, while desirable and of great value, can be done at intervals only, and, consequently, pathogenic organisms may enter the raw milk for varying periods before the condition is discovered. Raw milk may also become contaminated by disease bacteria

from other sources, such as flies and contaminated water and utensils, and no practicable frequency of inspection would prevent such contamination. It is not feasible to perform routine bacteriologic tests on raw milk to determine the presence or absence of all the pathogens which might be present. Even if simple test procedures were available, it is difficult to visualize any practicable testing frequency that would give positive assurance that the raw milk would always be free from infection. Accordingly, it is obvious that milk should be pasteurized to make it safe. This viewpoint is supported by the practically unanimous opinion of medical, public health and nutritional authorities.⁸

Pasteurization is performed by heating every particle of milk to at least 143 F. and maintaining this temperature for at least thirty minutes, or to at least 160 F. maintained for at least fifteen seconds. It has been proved that these time-temperature combinations, if actually applied to every particle of milk in approved and properly operated equipment, will devitalize all milk-borne pathogens.⁹

That pasteurization is economical and feasible has been proved by its widespread use. More than 75 per cent of the market-milk supply of American communities of over 1,000 population is pasteurized.¹⁰ The objections that have been raised to pasteurization are unsound. The average consumer is not able to detect any flavor difference when asked to choose, on "blind-fold test," between raw and pasteurized samples of high quality milk from the same source. Pasteurization does not, as recently charged, destroy the "friendly bacteria" while leaving the pathogens unharmed.

Although pasteurization is a heat treatment far less severe than that given to most foods during cooking, it is often claimed that pasteurization seriously reduces the nutritive value of milk, and various experimental results purporting to show injury to individual constituents of milk are often cited. Actually, definite reductions of nutritive elements due to pasteurization have been proved in only a few instances, and these reductions have not been shown to affect significantly the over-all value of milk in the diet.

Some investigators have reported that there is a slight loss of calcium due to pasteurization; another found no discernible difference between raw and pasteurized milk, and still others observed that calcium and phosphorus were as readily available in pasteurized as in raw milk.¹¹ The alleged losses of calcium are less than the natural variations of calcium in raw milk. Also, it might be pointed out that cow's milk, even if the alleged losses be accepted for the sake of argument, is nevertheless a much richer source of calcium than human milk.

Milk is not regarded as a good source of iodine, for the iodine content of milk is small and variable, ranging from 0.001 to 0.275 parts per million.¹² Nevertheless, a report that pasteurization causes a loss by volatilization of 20 per cent of the iodine in milk has been cited as evidence that pasteurization is detrimental to the food value of milk. Perusal of the original report reveals that the milk was held for thirty minutes at 158 F.—15 degrees above the present day pasteurization standards—and thus was subjected to a heat treatment considerably severer than the modern pasteurization process.¹³

No evidence has been found in the literature of any loss of vitamin A, or carotene,¹⁴ or of any lowering of the vitamin D content^{15a} due to pasteurization.

Although it is frequently claimed that vitamin B₁, or thiamine, is reduced 25 per cent by pasteurization, by the holder process, a reduction of about 10 per cent is oftener reported in the recent literature.¹⁴ In a study in 1945,¹⁵ a loss of only 3 per cent was reported in the case of milk pasteurized by the high temperature-short time method. With increasing interest in fortified flour and cereals, the slight loss of vitamin B₁ is of little significance.^{11b}

It has been claimed that pasteurization destroys from 9 to 16 per cent of vitamin B₂. Perusal of the original report reveals the statement:

Since it is customary, during commercial processing of milk, to carry out pasteurization by heating the raw milk in a thin film, during which time it may be exposed to light in the plant and therefore subject to considerable riboflavin destruction, the loss of the vitamin during this treatment has been investigated.¹⁶

In the United States it is almost universal practice to pasteurize market milk in pasteurizers which are completely covered, to exclude possible contamination, and it is therefore believed that the reported losses of 9 to 16 per cent would not occur under the latter conditions. In fact, recent reports generally agree that there is no significant loss of riboflavin as a result of pasteurization by either the high temperature-short time method or by the holding method.¹⁴ For example, in the experiments in 1945 by Holmes and his co-workers¹⁵ there was no loss in the riboflavin content of milk pasteurized by the high temperature-short time method, and it was reported that earlier studies by some of the same investigators revealed a loss of only 2 per cent when milk was pasteurized for thirty-three minutes at 144 F. in a stainless steel pasteurizer. Riboflavin is sensitive to light, and considerable loss of riboflavin results when milk is exposed to light, as in glass bottles left on the customer's porch in the sunlight for some time. However, it should be emphasized that these losses are not due to pasteurization.

Pyridoxine and nicotinic acid are very stable compounds, and, therefore, no loss of these factors is to be expected from pasteurization. Pantothenic acid is somewhat more labile, but preliminary results indicate that pasteurization does not inactivate it. Professor

Peterson has determined the biotin content of milk before and after pasteurization and observed no difference.^{11b}

Destruction of as high as 50 per cent of the vitamin C, due to pasteurization, has been claimed. The recent literature indicates that the destruction during pasteurization by the holder method is considerably less than 50 per cent and is probably in the neighborhood of 20 per cent.¹⁷ Data given by Holmes and his co-workers¹⁵ indicate vitamin C losses of 18.7 per cent and 18.3 per cent due to pasteurization of milk at 143 F. for thirty minutes in stainless steel pasteurizers. These figures represent the results obtained on two different mixed herd milks over eighteen month periods in 1938 and 1943. Elimination of copper from pasteurizing plant equipment is reducing the loss of vitamin C during pasteurization by the holder method, for traces of copper decidedly accelerate that action. Elvehjem stated that the presence of copper has a greater effect on vitamin C than heating.^{11b} The experiments in 1945 of Holmes and his co-workers showed no loss of vitamin C due to pasteurization of milk by the high temperature-short time method. Vitamin C is adversely affected by oxygen and light, and there are numerous opportunities for loss of the vitamin in the production, processing and distribution of milk, raw or pasteurized. For example, Wilson^{17a} referred to a study in which the vitamin C contents of grade A raw milk and of ordinary pasteurized milk after one day's storage were compared at different times of the year, and the average content actually was higher in the pasteurized milk than in the raw milk.

An adverse effect on vitamin E by pasteurization appears unlikely, in view of its resistance to heat treatment when present in wheat germ oil.¹⁸ Elvehjem reported indications of a slight deficiency of vitamin E, and perhaps vitamin K, when dogs are maintained solely on heat-treated milk through the reproduction period,¹⁹ but this observation does not appear to be of practical concern in human nutrition.

The effect of pasteurization on the mineral and vitamin constituents of milk may be summarized briefly as follows: No significant effect on the minerals of milk has been proved; vitamins A and D and pyridoxine, nicotinic acid, pantothenic acid and biotin are believed to be unaffected by pasteurization; vitamin B₂, or riboflavin, and vitamins E and K are practically unaffected; vitamin B₁, or thiamine, is reduced 3 to about 20 per cent, depending on the pasteurizing methods used, and vitamin C is reduced by an amount ranging from a small value to perhaps 20 per cent, depending on the methods and precautions observed in processing. Thus, the only appreciable losses are those of vitamins C and B₁, and these losses are not believed to be significant from the over-all nutritional standpoint. Milk is not a rich source of these vitamins, and adequate diets should contain foods other than milk, including such items as citrus fruits for vitamin C and whole grain or enriched products for thiamine.

COMMENT

It should be emphasized that milk is seldom used as the sole article of diet; hence, the physician is not so much interested in the precise quantitative effect of

pasteurization on individual constituents of milk as in the over-all nutritive value of pasteurized milk. Is pasteurized cow's milk as valuable as raw cow's milk in the diet of human beings? In order to determine the effect on growth of raw and pasteurized milk, many experiments have been conducted in America and England on children, calves, pigs, mice and rats. The experiments have been critically reviewed by Wilson,^{17a} who summarized them essentially as follows: Many of the studies have been faulty in design and execution, and the conclusions cannot be accepted without reserve. It is difficult to make satisfactory comparisons, because cow's milk is not a perfect food for any of these animals. An exclusive milk diet for a prolonged period is likely to be followed by anemia, rickets, scurvy or other disturbances. However, several experiments have been carefully conducted between groups of animals fed on raw or pasteurized milk with just a sufficient supplement to prevent the development of nutritional disease. Experiments on rats have not established a definite diminution in the total nutritive value of cow's milk as a result of pasteurization. The observations on mice are difficult to interpret, since the behavior of the animals appeared to depend on the way in which the milk was fed, but suggest that if any difference does exist between raw and pasteurized milk, it must be small and could be determined only by the use of large numbers of animals. Experiments on a total of 250 calves by six different groups of workers produced conflicting individual results, but when all the observations were combined it was observed that the mean increase in weight of the animals receiving raw milk was 1.232 pounds (about 0.559 Kg.) per day as compared with 1.273 pounds (about 0.578 Kg.) per day for those receiving pasteurized milk. It was observed, incidentally, that pasteurization of tuberculous milk protected the calves from contracting the infection. In the most recent comparison in children, little difference was observed between those receiving raw and those receiving pasteurized milk. On the average, the children receiving raw milk gained slightly more in weight and those receiving pasteurized milk gained slightly more in height, but the differences were not significant.

Wilson concluded that the results of various experiments with different animals, including children, are in general accord and fail to show that the pasteurization of milk by the holder method has any significant effect in lowering its total nutritive value for the growing animal.

McCollum²⁰ pointed out:

The opponents of pasteurized milk have conspicuously failed to make a case against it in favor of the raw product. The decided lessening of incidence of intestinal troubles and contagious diseases carried by raw milk through pasteurization makes it hard to understand how opposition can longer be justified.

He also stated:

Since the effect of pasteurization on the food value of milk is too slight to be apparent even in specially designed experiments, and is not apparent in observations on children living under ordinary American conditions, there is no valid argument which can be brought forward in support of the marketing of raw milk for the general population.

It appears obvious that American physicians and health authorities are justified in recommending that all milk be pasteurized.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

The Council has authorized publication of the following reports.

AUSTIN SMITH, M.D., Secretary.

METHAPYRILENE HYDROCHLORIDE GENERIC DESIGNATION FOR N,N-DIMETHYL-N'-(ALPHA-PYRIDYL)-N'-(ALPHA-THENYL)ETHYLENEDIAMINE HYDROCHLORIDE AND PROTECTED NAME THENYLENE HYDROCHLORIDE (ABBOTT LABORATORIES):

In the consideration of two brands of N,N-dimethyl-N'-(alpha-pyridyl)-N'-(alpha-thenyl) ethylenediamine hydrochloride, the Council was obliged to determine a satisfactory generic name. After due consideration, the term methapyriline hydrochloride was chosen. The Council has voted to accept a brand of this agent marketed by the Abbott Laboratories under the protected name "Thenylene Hydrochloride." The protected name proposed by another firm was found to be objectionable and has not been recognized.

METOPON HYDROCHLORIDE GENERIC DESIGNATION FOR METHYLDIHYDROMORPHINONE HYDROCHLORIDE

The Council recently published a paper on Metopon (J. A. M. A. May 22, 1948, p. 365), prepared by Dr. Nathan B. Eddy, Secretary of the Committee on Drug Addiction and Narcotics of the National Research Council, without having first formally published its recognition of the generic term. Since this term has been in use for some time by the U. S. Public Health Service for this preparation of methyldihydromorphinone hydrochloride and since there appears to be no objection to its use, the Council adopted the foregoing statement of recognition and authorized its publication.

NEW AND NONOFFICIAL REMEDIES

The following articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Non-official Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

LIQUID PETROLATUM-U.S.P. (See New and Non-official Remedies 1947, p. 320).

The following dosage forms have been accepted:

THE E. L. PATCH COMPANY, BOSTON

Emulsion Kondremul (Plain): 500 cc. bottles. An emulsion of mineral oil and Irish Moss (*Chondrus Crispus*).

Emulsion Kondremul with Cascara: 400 cc. bottles. An emulsion of mineral oil with nonbitter extract of cascara and Irish Moss (*Chondrus Crispus*).

Emulsion Kondremul with Phenolphthalein: 500 cc. bottles. An emulsion of mineral oil with phenolphthalein and Irish Moss (*Chondrus Crispus*).

NICOTINAMIDE-U.S.P. (See New and Nonofficial Remedies 1947, p. 514).

The following dosage forms have been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Solution Nicotinic Acid Amide: 100 mg. per cc., 10 cc. vials. Preserved with chlorobutanol 5 mg.

Tablets Nicotinic Acid Amide: 100 mg.

RIBOFLAVIN-U.S.P. (See New and Nonofficial Remedies 1947, p. 511).

The following dosage form has been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Tablets Riboflavin: 5 mg.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Sept. 8, 1948.

Party to Attend Hospital Dedication

Led by heads of the Army, Navy and Air Force medical departments, a Washington group bound for dedication ceremonies at Tripler General Hospital, Honolulu, is scheduled to depart from the Capital by plane on Labor Day. Members of the party will attend sessions of the Pan Pacific Surgical Association on September 9, as well as the Tripler dedicatory program on the following day. They will be joined in Honolulu by Dr. Ernst E. Irons, President-Elect, and probably other representatives of the American Medical Association. The group will be composed of the following: Maj. Gen. Raymond W. Bliss and Rear Adm. Clifford A. Swanson, Surgeons General of Army and Navy, respectively; Maj. Gen. Malcolm C. Grow, Air Surgeon; Dr. W. P. Dearing, Deputy Surgeon General of the U. S. Public Health Service; Rear Adm. Joel T. Boone, executive secretary, Committee on Medical and Hospital Services of the Armed Forces; Brig. Gen. George E. Armstrong, Army Deputy Surgeon General; Maj. Gen. Norman T. Kirk, former Army Surgeon General; Col. Mary G. Phillips, chief of Army Nurse Corps; Rear Adm. Paul M. Albright, assistant chief, Bureau of Medicine and Surgery; Col. A. L. Tynes, chief of Army hospital construction; Maj. Gen. John M. Willis, commandant of Brooke Army Medical Center; Col. William Powell, member of the Hawley Board's executive committee; Dr. Wilburt C. Davison, dean of Duke University School of Medicine; Dr. Herman G. Weiskotten, dean, Syracuse University College of Medicine; Dr. Carleton Mathewson, San Francisco Hospital; Gerald G. Gross, editor of Washington Report on the Medical Sciences and public relations consultant to Gen. Bliss; Col. Elbert DeCoursey, of Brooke Army Medical Center; Brig. Gen. Leonard Heaton, chief of surgery at Letterman General Hospital.

General Heaton, Col. DeCoursey and Dr. Mathewson will join the party in San Francisco. From Honolulu certain military members of the contingent will continue to Guam to study possibilities of consolidating Army and Navy hospital facilities on the island. Included in this group will be General Bliss, Admirals Swanson, Boone and Albright, and Col. Powell.

Dr. Draper Joins Retirement Fund Staff

Although neither American Red Cross nor United Mine Workers had issued any announcement of the transfer as of August 28, Dr. Warren F. Draper is retiring from his Red Cross post and will join the United Mine Workers Welfare and Retirement Fund staff early in September. He will serve as executive officer of the fund's medical branch, in association with Dr. R. R. Sayers, chief. For the past two years Dr. Draper has been with Red Cross as deputy to Dr. G. Foard McGinnes, vice president for medical services. During the first half of that tenure, he was on loan from U. S. Public Health Service, of which he formerly had been Deputy Surgeon General. On his statutory retirement, for age, from the U. S. Public Health Service in 1947, he remained in Red Cross service. During a great part of World War II, Dr. Draper was on assignment to Army forces overseas with the rank of major general.

Report of Poliomyelitis Cases

Encouraged by a decline in the number of reported cases of poliomyelitis, the U. S. Public Health Service authorities are hopeful—but still far from certain—that the peak for 1948 has been reached. During the week ended August 21, a total of 1,307 new cases was reported to Washington. This compared with 1,409 for the previous week and marked the first weekly decline since May 22. Also, it was the fourth consecutive week with a case figure below that for the corresponding seven day period in 1946, which was the nation's most serious poliomyelitis year since 1916. Another heartening development was the reduction in case reports from Texas, North Carolina and

California, the states that have been hardest hit this year. For the week ended August 21, only three states reported increases of 10 or more cases over the preceding week. They were New York, whose 99 new cases compared with 59 the previous week; Minnesota, up from 57 to 67, and Wisconsin, from 26 to 36. Rhode Island retained its distinction of being the only state in the Union where not 1 case of poliomyelitis had been diagnosed and reported this year up to August 21. The grand total for 1948 up to that date was 9,743 cases, compared with 3,221 for the same period in 1947 and 8,841 in 1946. The five year median is 4,308.

R.O.T.C. Units

In preparation for the coming academic year, the newly assigned Medical, Dental, Veterinary and Medical Service Corps officers who will command Army R.O.T.C. units in professional schools this fall assembled at the Pentagon August 25-27 for an orientation conference. They were addressed and "briefed" by division chiefs in the Surgeon General's Office on Selective Service regulations, administrative duties and miscellaneous responsibilities.

Scheduled to have R.O.T.C. units in 1948-1949 are 51 medical schools, 18 dental schools, 6 colleges of veterinary medicine and 4 pharmacy schools. Eight of the medical schools will be joining the program, now entering its third year, for the first time. They are Boston, Columbia, Harvard, Kansas, South Carolina, Tulane, Washington (Seattle) and Emory.

The Army has never had R.O.T.C. instruction in pharmacy schools before, and this will mark the end of a fifteen year hiatus in dental and veterinary schools, where it was discontinued in 1933.

Critical Pharmaceuticals

Two pharmaceutical items are included among the twenty-eight critical materials which are on the Munitions Board's stockpiling list for the purchase period ending October 1, it has been announced by the National Military Establishment. The purchase program calls for delivery before June 30, 1949.

"While the Munitions Board plans the stockpiling program," said the announcement, "companies having strategic and critical materials which can be spared for the national stockpiles should deal directly with the Bureau of Federal Supply, Department of the Treasury, which makes the actual purchases."

The pharmaceutical items and the quantity scheduled to be contracted for by October 1 are as follows: quinidine, 6,000 ounces; castor oil, 15,000,000 pounds.

Committee Solicits Complaints of Government Doctors

A spokesman for the Hoover Commission's medical services committee, which is studying federal medical care activities, reports excellent response to the questionnaire which was mailed in mid-August to physicians, dentists and nurses on government payrolls, or who formerly were in federal service. The purpose of the poll was to obtain candid comment on the way that their skills were or are being utilized in the Army, Navy, Veterans Administration and U. S. Public Health Service and to stimulate constructive criticism.

The replies will help the committee, whose head is Tracy S. Voorhees, Assistant Secretary of the Army, in the formulation of its forthcoming report, which will recommend certain administrative reforms in federal medical and hospital functions. A sampling of several thousand physicians, dentists and nurses will be covered in the questionnaire survey, which is under the immediate supervision of Dr. Edward D. Churchill, chairman of the medical man power subcommittee.

Labor Department Reports on Insurance Plans

A report by the Department of Labor discloses that upward of 3,000,000 American workers are covered by health-pension insurance contracts with their employers. This is a fivefold increase over the 1945 figure, according to the Bureau of Labor Statistics survey on which the report is based.

GOVERNMENT SERVICES

ARMY

MEDICAL MEETING IN KOREA

The monthly meeting of Army Medical Department officers stationed in Korea on July 21 was sponsored by the Department of Public Health and Welfare, USAMGIK. The sixty officers and twenty-five civilian physicians and nurses who attended visited the Sun Wha City Contagious Disease Hospital in Seoul, where Dr. Y. S. Yun presented cases illustrating the various stages of syphilis and Dr. C. M. Myun, discussed the treatment of tuberculosis as carried out at the hospital. In the contagious disease section, several cases of smallpox and diphtheria were observed. In the afternoon, Dr. P. S. Han discussed the vital statistics available in South Korea. Lieut. William I. Rolph, M.C., Advisor to the Department of Public Health and Welfare, discussed the recent movement of refugees from Manchuria to South Korea, outlining the measures taken for the prevention of diseases among them. Captain M. H. Heeren, Nursing Advisor, outlined the means taken to bring the nursing standards and social position of Korean nurses up to a level comparable to those of the United States. Dr. H. C. Mason, supervisor, conducted a tour of the National Biological Laboratories, which are industriously engaged in raising public health and therapeutic standards in South Korea. A visit was made also to the Receiving Home for Orphans, where the methods of care and disposition of the children were outlined by Mr. M. W. Scherbacher.

SPECIALIST RATING IN PREVENTIVE MEDICINE

Medical officers who want to be certified as specialists in preventive medicine may now submit applications to the Interim Board of Preventive Medicine which will administer the examinations and certification. This board was formed by joint action of the Surgeons General of the Army, Navy and Public Health. The qualifications, among other things, include graduation from a medical school and internship in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association or by the Army or Navy, the degree of Master of Public Health or its equivalent, membership in the American Medical Association and experience in a responsible position in the field of public health or preventive medicine. The examinations will be held during the fall of this year or the spring of 1949.

POSTGRADUATE COURSES

Fifty-eight additional Army Medical Department officers will shortly begin courses in various subjects in civilian schools and hospitals. In this number are five lieutenant colonels, one major, three captains, forty-eight first lieutenants, and one second lieutenant, representing various corps of the Medical Department.

NAVY

RESEARCH AT GREAT LAKES ON RESPIRATORY DISEASES

A Navy medical research unit designed to develop methods of respiratory disease control is being established at the Naval Training Center, Great Lakes, Ill. The unit will conduct laboratory tests of measures designed to control the spread of the common cold, tonsillitis, scarlet fever, influenza and pneumonia. Clinical records of all cases of such diseases at the Naval Training Center will be correlated with data on climate, living conditions, physical fitness and diet. The Naval Training Center at Great Lakes, having about 25,000 officers and enlisted men, was chosen as an ideal location for the study of epidemiology. While medical treatment and isolation have reduced fatalities from respiratory ailments to a minimum, these diseases remain the greatest annual cause of man-work days lost by illness.

The research unit is being installed in permanent quarters and when completed will offer complete facilities necessary for the studies. The main laboratory is designed to provide office space and laboratories where the bacteriologic, virologic, serologic and chemical studies can be carried out. Observations on the personnel of the naval center will be carried out in the medical dispensaries throughout the station with the cooperation of the medical department of the Training Center. Conversion of laboratory buildings will be completed about Jan. 1, 1949.

The research staff will consist of four Navy medical officers, seven civilian scientists, sixteen naval enlisted technicians and eight civilian technicians. Consultants will be associated with the unit and by periodic visits will advise in the direction of the studies. Lieutenant Commander John R. Seal of the Navy Medical Corps is officer in charge of the unit. Other Navy medical research units are stationed in California and Egypt. Unit 1, composed mostly of civilian scientists, is located at the University of California. Directed by Captain Albert Krueger, MC, U. S. N. R., a reserve medical officer now on inactive duty, this unit is engaged in studying bacteriology, particularly virus growth. Unit 3, under Commander R. A. Phillips, is stationed in Cairo, Egypt. This unit is conducting research on parasitic diseases and other ailments native to Northern Africa.

ACCEPTED FOR POSTGRADUATE INSTRUCTION

The following medical officers have been accepted for postgraduate instruction at the institutions indicated: Commander John J. Eberhart, Nashville, Tenn., residency in psychiatry at the University of Louisville School of Medicine in Kentucky; Commander Vinton Hall, South Pasadena, Calif., course in dermatology and syphilology at the University of Southern California in Los Angeles; Commander Russell F. Sanders, Williams Bay, Wis., course in pathology at the National Naval Medical Center, Bethesda, Md.; Commander Roger D. Sherman, Briarcliff Manor, N. Y., residency in psychiatry at the Naval Hospital in Philadelphia; Lieut. Richard B. Leander, St. Paul, course in psychiatry at the Pennsylvania Hospital in Philadelphia, and Lieutenant (jg) Peter W. Schneider, Laurel, Miss., residency in pediatrics at the Naval Hospital in Long Beach, Calif.

NEW REGULAR OFFICERS

The following naval medical officers have been accepted for transfer from the Naval Reserve to the Regular Navy: Lieut. (jg) David M. Butler, Provo, Utah; Lieut. (jg) John G. Esswein, New York; Lieut. (jg) John S. Neill, Valley Station, Ky., and Lieut. (jg) John M. Packard, Saranac Lake, N. Y.

PERSONALS

Cpts. Everett M. George and Robert B. Team and Lieut. Comdr. Julian M. Jordan, Medical Corps, now on the retired list, have volunteered to return to active duty and have been assigned.

Lieut. (jg) Jules H. Bogaev of the Naval Reserve has been ordered to active duty at Great Lakes, Ill.

Lieut. (jg) Harold A. Davis of San Diego, Calif., has gone on active duty at the Naval Hospital, San Diego, Calif., from an inactive Reserve status.

Capt. Francis D. Walker, M.C., Retired, of Brunswick, Maine, has returned to active duty at his own request and has been assigned to the Receiving Station, San Diego, Calif.

VETERANS ADMINISTRATION

RESIDENCIES IN PSYCHIATRY AVAILABLE

Residencies in psychiatry are available at the Veterans Administration Hospital, Gulfport, Miss. Training will be given at the hospital and in New Orleans under the supervision of Tulane University and Louisiana State University Schools of Medicine. The program will include didactic and clinical instruction in all phases of psychiatry and basic neurology, with experience in the techniques of treating neuropsychiatric adults and children. Applications should be addressed to Dr. H. W. Kostmayer, Chairman of the Combined Deans' Committee, Tulane University School of Medicine, New Orleans.

CONTRACTS FOR HOSPITALS

The contract for the construction by the Veterans Administration of a two hundred bed hospital at Grand Island, Neb., has been awarded on a low competitive bid of \$5,244,854.

The contract for the construction of a two hundred and fifty bed Veterans Administration hospital at Big Springs, Texas, has been awarded to the low bidder for \$5,712,739.

Contracts have been let for the general construction of the two hundred bed Veterans Administration general hospital at Fort Wayne, Ind., to the low bidder for \$4,682,500.

Contracts for the main construction work on the 1,000 bed hospital at Buffalo, N. Y., have been awarded, the successful bid being \$9,287,000 for the main building; the heating and ventilating contract was for \$1,334,497 in addition, and the plumbing contract \$1,297,344.

The contract for the mechanical construction of the four hundred and fifty bed general hospital at Shreveport, La., has been awarded to the lowest bidder for \$2,242,450.

MEETING OF ADVISORY BOARD

The next quarterly meeting of the Veterans Administration national advisory board, which is under the chairmanship of Dr. Charles W. Mayo, Rochester, Minn., will be in Washington, D. C., September 13. A recent appointment is that of Dr. Robert A. Kimbrough Jr., of Philadelphia, succeeding Dr. Paul Titus of Pittsburgh, who resigned.

PERSONALS

Dr. Horace B. Cupp, for a long time on the staff of the Johnson City, Tenn. veterans' hospital, has been named assistant medical director for the Southeastern Branch of the Veterans Administration, which supervises fifteen hospitals and six regional offices in the five Southeastern states. Dr. Cupp served in the Army in the recent war in command of the 63d Station Hospital in Australia and later as commanding officer of a hospital ship.

Dr. David E. Quinn, formerly manager of the veterans' hospital at Oteen, N. C., has assumed his new duties as medical director of the Northwest Branch of the Veterans Administration with headquarters at Seattle.

Dr. J. G. Bohorfoush has resigned as medical director of the Jefferson Tuberculosis Sanatorium, Birmingham, Ala., to accept a position with the Veterans Administration in Atlanta, Ga.

Dr. George S. Peters has resigned as chief of the Surgical Service at the veterans' hospital, Montgomery, Ala., and will enter private practice in that city.

Dr. Robert A. Houston, Sunbury, Pa., has been appointed chief of medical services of the veterans' hospital at Lebanon, Pa.

PUBLIC HEALTH SERVICE

COURSES IN LABORATORY DIAGNOSIS

The Public Health Service announces a second four weeks' course in the laboratory diagnosis of tuberculosis to be given November 15-December 10 at the Communicable Disease Center, in Atlanta. This course is open to all grades of employed laboratory personnel, although first consideration will be given to those from local and state public health service departments. A third six weeks' course on laboratory diagnosis of parasitic diseases will be given at the above address October 11-November 19. There are no tuition fees but travel and living expenses must be paid by the individual. Applications for the courses should be made as far in advance as possible to the Chief, Laboratory Division, Communicable Disease Center, 291 Peachtree Street, Atlanta, Georgia.

APPOINT DIRECTOR OF NATIONAL HEART INSTITUTE

Surgeon General Leonard A. Scheele announces the appointment of Dr. Cassius J. Van Slyke as Director of the National Heart Institute, under the general supervision of Assistant Surgeon General R. E. Dyer, Director of the National Institutes of Health. Dr. Van Slyke will be responsible to the Surgeon General for coordination of all heart disease activities in the Public Health Service. He will represent the Service in maintaining relations with professional societies, volunteer agencies and other civil groups interested in the heart disease program.

The National Heart Institute was created by an Act of Congress, which was approved by the President June 15, 1948. The law authorizes the Public Health Service to develop a program and promote the attack on cardiovascular diseases. The program will include research, financial aid to research institutions and training of professional personnel, fellowships for individual scientists and grants-in-aid and technical assistance to the states for the development of heart disease control services.

The National Heart Act also directs the appointment of a National Advisory Council to be composed of outstanding scien-

tists and clinicians in cardiovascular diseases and representatives of the public. The new Institute will have its headquarters at the National Institutes of Health, Bethesda, Md.

Dr. Van Slyke was graduated from the University of Minnesota Medical School and in 1932 was commissioned in the Regular Corps of the Service. One of his first assignments was investigation of encephalitis in St. Louis; from 1936 to 1944, he pursued a distinguished career of research at the Venereal Disease Laboratory of the Public Health Service at Stapleton, N. Y. In 1945, he was placed in charge of the Research Grants program of the National Institutes of Health. Dr. David E. Price, who succeeds Dr. Van Slyke as Chief of the Division of Research Grants and Fellowships, took his medical degree at the School of Medicine, University of California, and was commissioned in the Regular Corps of the Public Health Service. In 1947 he was made Chief, Cancer Grants Branch of the National Cancer Institute.

ADVISORY MENTAL HEALTH COUNCIL

The appointment of Dr. Leo H. Bartemeier, associate professor of psychiatry, Wayne University College of Medicine, Detroit, and Dr. Carlyle Jacobsen, Ph.D., dean of the graduate school, State University of Iowa, Iowa City, to the National Advisory Mental Health Council has been announced. They will succeed Dr. David M. Levy, New York, and Dr. Edward A. Strecker, Philadelphia, whose terms on the council expired on June 30. Dr. David Levy has been appointed to serve on the Research Study Section, an advisory body of the council; Dr. Grover F. Powers, professor of pediatrics, Yale University School of Medicine, New Haven, Conn., also has been appointed to the Research Study Section, replacing Dr. Charles A. Jancway, professor of pediatrics, Harvard Medical School, Boston, on the latter's resignation. The National Advisory Mental Health Council, comprising six leading scientific authorities, makes recommendations to the Surgeon General on matters relating to the activities of the U. S. Public Health Service in the field of mental health.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

International College of Surgeons.—The Alabama section of the International College of Surgeons will meet in Birmingham, September 30, in conjunction with the Jefferson County Medical Society and the Southern Research Institute at the Jefferson-Hillman Auditorium. Guest speakers include:

Herbert Acuff, Knoxville, Tenn., Future of Isotopes in Medicine and Surgery.

F. Bayard Carter, Durham, N. C., Endometriosis.

J. Barrett Brown, St. Louis, Management of Facial Injuries.

Albert A. Berg, New York.

Allen F. Voshell, Baltimore, Orthopedics.

Edgar W. Davis, Washington, D. C., Intrapulmonary Tumors.

At the Wednesday evening session, Dr. William Dameshek, Boston, will discuss leukemia. Members of the Alabama State Medical Society are especially invited to this meeting.

CALIFORNIA

New Psychiatric Clinic.—The Berkeley State Mental Hygiene Clinic, associated with the University of California, which has opened temporary quarters in the Cowell Hospital, is part of the State Department of Mental Hygiene and is financed by funds provided under the National Mental Health Act. The clinic is under the direction of Dr. Portia Bell Hume.

Cancer Research Grants.—Five research projects at the University of California, Berkeley, are to be supported by a \$21,364 grant from the American Cancer Society. The research, which will be directed toward learning the cause of cancer, is being carried on by Dr. Herbert M. Evans, director of the Institute of Experimental Biology, David M. Greenberg, Ph.D., professor of biochemistry, Paul L. Kirk, Ph.D., professor of biochemistry, and Harold Tarver, Ph.D., assistant professor of biochemistry.

Dr. Addis Honored.—The May issue of the *Stanford Medical Bulletin* is dedicated to Dr. Thomas Addis, professor of medicine emeritus at Stanford University School of Medicine, and contains thirty-two articles by associates, students and fellow workers in the field of renal disease. Dr. Addis is a former Carnegie Research scholar and fellow, and in 1942 was awarded the Cullen Prize by the Royal College of Physicians in Edinburgh. He had been a member of the faculty at Stanford University School of Medicine since 1911.

ILLINOIS

Civil Service Positions Open.—The Illinois Civil Service Commission announces eighteen examinations for physicians, nurses, dentists and health educators. Appointments to be filled include positions in welfare hospitals and schools throughout the state, and in various divisions and field offices in the department of public health. State residence requirements are waived for most of these examinations. September 25 is the final date for applying. These examinations, carrying eligibility for permanent civil service appointments, will be held October 16 and 23. Official application forms and more detailed information may be obtained from the Illinois Civil Service Commission, Armory Building, Springfield.

Postgraduate Conference in Harrisburg.—The Postgraduate Education Committee of the Illinois State Medical Society will sponsor a postgraduate conference at the Harrisburg Country Club, Harrisburg, September 22, with the Saline County Medical Society acting as host. The conference will open with a luncheon, after which the following speakers will participate:

Oswald P. J. Falk, St. Louis, Management of Cardiovascular Problems.

Ransom R. Buchholz, Evansville, Ind., Congenital Diseases of the Newborn.

Danely P. Slaughter, Chicago, Office Diagnosis of Accessible Cancer.

Samuel J. Taub, Chicago, Diagnosis and Treatment of Asthma.

Noel G. Shaw, Evanston, The Rh Factor in the Newborn.

F. Garm Norbury, Jacksonville, Acute Infections of the Nervous System.

A round table discussion and social hour will conclude the afternoon's program. At the dinner Dr. Richard K. Gilchrist, Chicago, will speak on "Surgery of the Colon from the General Practitioner's Standpoint."

Chicago

Dr. Kordenat Goes to Texas.—Dr. Ralph A. Kordenat, formerly associate professor of surgery with the University of Illinois College of Medicine, Chicago, has been appointed to the medical staff, Dallas, Texas, branch office of the Veterans Administration, and will assist in the supervision of the Veterans Administration surgical service in Texas, Louisiana and Mississippi hospitals with permanent headquarters in Dallas. Dr. Kordenat was graduated from the University of Illinois College of Medicine in 1922 and did postgraduate work in London and Berlin. He is one of the founders of the American Board of Surgery. He served during World War I in the U. S. Army and during World War II was vice chairman of the Procurement and Assignment Service for Physicians in Illinois.

Public Lectures on Nutrition.—The second annual public meeting on nutrition, sponsored by the Chicago Medical Society and cooperating organizations, will be held at the John B. Murphy Memorial Amphitheater, Chicago, October 13-14. Speakers include:

John P. O'Neil, Chicago, The Wedding of the Sciences in Human Nutrition.

Ira Allison, Springfield, Mo., Undulant Fever.

William H. Schrell Jr., Bethesda, Md., A National Public Health Nutrition Program.

Thelma E. Porter, Ph.D., Chicago, Your Dollar and Your Diet.

Icie Macy Hoobler, Ph.D., Detroit, Maternal Nutrition and Child Health.

William J. Darby, Nashville, Tenn., Obesity.

Ansel B. Keys, Ph.D., Minneapolis, Caloric Nutrition.

Christian P. Segard, Leonia, N. J., Fat Free Certified Milk.

Herman N. Bundesen, Chicago, Public Health and Food.

A round table discussion with questions from the floor will take place each afternoon.

LOUISIANA

Appoint President of State Board.—Dr. William V. Garnier, Bastrop, has assumed his duties as president of the state board of health, succeeding Dr. Waldo L. Treuting, who was appointed professor of public health administration at Tulane University of Louisiana School of Medicine, New Orleans, effective July 1. Dr. Garnier is a graduate of Tulane, 1925. Dr. Treuting, a graduate of Tulane, 1934, has served in the health department as president since July 1946.

MINNESOTA

General Practitioner Honored.—The University of Minnesota Medical School recently presented an "Outstanding Achievement" medal to Dr. William W. Will of Bertha at an alumni dinner in Minneapolis. Dr. Will was also recently named by the state medical association for the American Medical Association outstanding general practitioner award.

Course in Tuberculosis.—Tuberculosis and other diseases of the chest will be reviewed in a three day course for general practitioners at the University of Minnesota Center for Continuation Study, Minneapolis, October 18-20. The course is sponsored by the American Trudeau Society, the University of Minnesota, Minneapolis, and the state and county Christmas Seal organizations.

MISSOURI

Clinical Conference.—The Fall Clinical Conference of the Kansas City Southwest Clinical Society will be held in the Municipal Auditorium, Kansas City, October 4-7. Guest speakers include:

William H. Amspacher, Washington, Utilization of Medical Corps Officers in the United States Army.

Ignacio Chavez, Mexico City, Mexico, Coronary Heart Disease.

Willard R. Cooke, Galveston, Texas, Rationalism in Regard to Gynecologic Operations.

George Crile Jr., Cleveland, Treatment of Peritonitis and Intra-Abdominal Abscess.

William Dameshek, Boston, Diagnosis of Anemia.

R. Arnold Griswold, Louisville, Ky., Treatment of Traumatic Wounds of Soft Tissues.

Howard T. Karsner, Cleveland, Acute Inflammations of Arteries.

L. Chester McHenry, Oklahoma City, Perforation of the Esophagus.

Samuel F. Marshall, Boston, Gastric Surgery for Peptic Ulcer.

Earl R. Miller, San Francisco, Use of Radioactive Iodine in Medicine.

Ralph V. Platou, New Orleans, Penicillin Therapy of Congenital Syphilis.

Herbert L. Pugh, Washington, D. C., Ideas for Future Use of the Medical Profession in a National Emergency.

Richard G. Scobee, St. Louis, The Doctor and the Cross-Eyed Child.

William A. Sodeman, New Orleans, Fever of Undetermined Origin.

James E. M. Thomson, Lincoln, Neb., What Fractures to Treat and What Fractures to Refer.

John B. Wear, Madison, Wis., Hydronephrosis — Symptoms and Diagnosis.

Daily round table luncheons will be held in medicine and surgery. Both scientific and technical exhibits will be on display.

NEBRASKA

Society of Anesthesiologists.—At a meeting in Omaha, May 12, the Nebraska Society of Anesthesiologists, a component member of the American Society of Anesthesiologists, Inc., was founded. Officers elected were: Dr. Dorothy Thompson, Omaha, president, and Dr. Kenneth E. Latterell, Omaha, secretary-treasurer.

Brigadier General Carroll Appointed Dean.—On September 1, Dr. Percy J. Carroll, St. Louis, retired brigadier general, will become dean of Creighton University School of Medicine, Omaha, and chief of staff at Creighton Memorial-St. Joseph's Hospital. He will hold the rank of professor of preventive medicine. He was appointed dean and professor of public health at the St. Louis University School of Medicine in 1946. During World War II he was commandant of the Army Medical Center of Manila and later Chief Surgeon of the Southwest Pacific Theater of Operations and the Far East. He received the Distinguished Service Medal for his work in evacuating the wounded from Manila. In 1944 he returned to the United States and assumed command of Vaughn General Hospital, Hines, Ill. He retired from the army in 1946.

NEW YORK

Personal.—Dr. John R. Williams, Rochester, on July 7 received Rochester's Museum 1948 Weisenbeck Memorial Award for his work in encouraging interest in hobbies in Rochester. Dr. Robert H. Broad, Binghamton health officer, was elected president of the New York State Association of Health Officers at its annual meeting in Saratoga Springs in July.

Appoint Deputy Health Commissioner.—Dr. Hollis S. Ingraham, director of the division of communicable diseases of the state department of health, has been named deputy commissioner. The present deputy commissioner, Dr. William A. Brumfield Jr., will become first deputy. Dr. Ingraham's position was added because of the department's expanding program.

Board of Arbitration.—The Oneida County Medical Society has approved the appointment of a medical board of arbitration to which insurance companies may submit physicians' bills which they believe to be excessive. The move was the result of sharp increases in automobile liability insurance rates recently effective in the area. The panel is made up of ten physicians. The medical society is reported to have appointed a committee to study the situation and make recommendations to the society. The society also plans to appoint a panel of physicians who will handle emergency calls relayed to them from police through the doctors' telephone exchanges.

Canandaigua Hospital Joins Medical Center.—Under an agreement reached by the officials of the Veterans Administration and the University of Rochester School of Medicine and Dentistry, the Canandaigua Veterans Administration Hospital becomes part of the university's Strong Memorial Hospital medical center. As a center of neuropsychiatric research, the Rochester hospital will aid the veterans' facility. A committee has been named to work out the details of the relationship: Dr. John Romano, professor of psychiatry, chairman; Dr. William S. McCann, professor of medicine; Dr. Paul H. Garvey, associate professor of medicine in neurology; Drs. Nils B. Hersloff and Edwin M. Levy, of the Canandaigua institution. The affiliation will also make it possible for the Veterans Administration patients to receive surgical treatment now unavailable.

New York City

Dr. Cissel Director of Surgery.—Dr. Benjamin M. Cissel, professor of clinical surgery at Long Island College of Medicine, has been named director of surgery of the college division at Kings County Hospital. His appointment fills the vacancy created by the recent promotion of Dr. E. Jefferson Browder to full professor and head of the department of surgery at the medical school.

Brooklyn "Healthmobile."—The Brooklyn Tuberculosis and Health Association has purchased a "healthmobile" for an information center and chest x-ray unit on wheels, as part of its drive to reduce tuberculosis in Brooklyn. Citizens of the borough may receive free tuberculosis information and roentgenograms for \$1. According to the *New York Times*, Everett M. Clark, president of the association, said that 15 persons died weekly in Brooklyn from tuberculosis and that there were almost 2,000 new cases each year. The association took some 38,000 roentgenograms of the chest last year.

Foreign Language Press Committee.—Dr. Kendall Emerson, president, New York Tuberculosis and Health Association, has announced the formation of a foreign language press committee to aid the association in its public relations pro-

gram. The new group will be headed by Sigmund Gottlober, director of the American Foreign Language Press, 258 Fifth Avenue. Dr. Herbert R. Edwards, executive director, New York Tuberculosis and Health Association, and Frederick Hodgson, public relations director, will serve as ex officio members. The committee, Dr. Emerson said, will be a continuing body functioning not only in fund raising but in carrying on year-round work on behalf of health education, tuberculosis case finding and rehabilitation.

OHIO

Postgraduate Seminars.—The committee on education of the Ohio State Medical Association will present three practical postgraduate seminars this fall: October 21, Elks Home, Chillicothe, "New Advances in Diagnosis and Treatment of Chest Diseases"; October 27, American Legion Hall, Lima, "Practical Cardiology"; November 3, Mansfield-Leland Hotel, Mansfield, "Practical Dermatology."

Anesthesiologists' Meeting.—The American Society of Anesthesiologists will hold a joint meeting with the Ohio Society of Anesthesiologists, October 1-2, at the Hotel Commodore-Perry, Toledo. Out of state speakers include: Drs. Robert A. Hingston, Memphis, Tenn., who will speak on "Hypospay"; John Adriani, New Orleans, "Practical Aspects of Chemistry of Anesthetic Drugs"; H. Boyd Stewart, Tulsa, Okla., "Practice of Anesthesiology," and Ivan B. Taylor, Detroit, "Intravenous Procaine." On Saturday a panel on cyclopropane will be held.

OKLAHOMA

Postgraduate Circuits.—The eighth and next to the last circuit in the two year postgraduate course in gynecology is under way in Oklahoma. Instructor for the Oklahoma State Medical Association sponsored postgraduate instruction is Dr. Joseph R. B. Branch, Macon, Ga. The next postgraduate instruction will begin shortly after Jan. 1, 1949, and will be in internal medicine.

Association Awards Fifty Year Pins.—All members of the Oklahoma State Medical Association who have been in active practice in excess of fifty years are being presented fifty year pins. The first twelve pins were presented at the annual meeting in May, and four more have been presented since that time to others of the twenty-six society members now eligible to receive the award. Special county society meetings are scheduled for the next few months to present the remaining pins. Dr. Clarence E. Northcutt, Ponca City, president of the Oklahoma State Medical Association, or councilors of the association will make the presentations.

PENNSYLVANIA

Emergency Service Setup.—Through Dr. Richard C. Kaar, president of the Milton Board of Health, a survey is being made of all local physicians to obtain their hours and file them with the Borough Police to provide an emergency roster.

Graduate Education Institute Begins.—Beginning this month, the second annual program of the Graduate Education Institute of the state medical society will be carried on in ten centers throughout the state to carry medical education to practicing physicians in rural areas. Teaching centers have been set up in Oil City, Johnstown, Williamsport, Harrisburg, Wilkes-Barre, Allentown, Erie, Washington, Clearfield and Lancaster. More than 1,000 doctors, chiefly from rural areas, will register for the season's course. Last year total registration was 850. Beginning in the fourth week of September, eight hours of intensive medical education will be presented each week in each center for a period of five weeks. In April the second half of the course will be given, making ten full days or eighty hours of class room lectures. The faculty will include 216 teachers from the University of Pennsylvania School of Medicine, Jefferson Medical College of Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, Temple University School of Medicine, Woman's Medical College of Pennsylvania, all of Philadelphia, and the University of Pittsburgh School of Medicine. This year the three days of instruction will feature diseases of infants and children. There will also be a day of lecturing on the general practice of medicine with some attention given to the application of radioactive substances in the treating of disease. Lectures begin on September 21 in Allentown, September 22 in Erie, Lancaster, Oil City, Washington, Wilkes-Barre and Williamsport, and September 23 in Clearfield, Harrisburg and Johnstown. The schedules are so arranged that if a doctor misses one session at the center nearest his home he can attend an identical session in a neighboring center on another date.

Philadelphia

Personal.—The King Christian X Medal of Liberation, Denmark, has been awarded to Bernard Spur, Ph.D., of the Children's Hospital of Philadelphia, in acknowledgment of his wartime aid to Danish children in Greenland.

Honored by the British.—Alfred N. Richards, LL.D., professor emeritus of pharmacology, University of Pennsylvania School of Medicine, who retired July 1 as vice president in charge of medical affairs, and Detlev W. Bronk, Sc.D., medical director of the Johnson Foundation and professor of biophysics at the university, were decorated with the Order of the British Empire at ceremonies at the British Embassy, Washington, D. C. Dr. Richards was decorated for his leadership as chairman of the Committee on Medical Research of the Office of Scientific Research and Development. Dr. Bronk received the honor "in recognition of his many outstanding contributions to the allied war effort." Dr. Harold G. Scheie, assistant professor of ophthalmology, and Dr. Henry C. Bazett, professor of physiology at the university, received the same decoration on earlier dates.

TENNESSEE

First Regional Postgraduate Medical Assembly.—The Nashville Academy of Medicine will conduct its first regional Postgraduate Medical Assembly in Nashville, October 6-7, for the benefit of all physicians in Tennessee and adjacent states. Twelve out of state essayists will discuss obstetrics, eye, ear, nose and throat, orthopedics, urology, plastic surgery, antibiotics, anemias, endocrinology, gynecology and radiology. Credit may be had by members of the American Academy of General Practice for attendance at this assembly. Reservations may be secured at the Andrew Jackson and Hermitage hotels.

Dr. Wilson Appointed Professor of Surgery.—Dr. Harwell Wilson was recently appointed professor and chief of the division of surgery at the University of Tennessee College of Medicine, Memphis. He received his M.D. degree at Vanderbilt University School of Medicine, Nashville, 1932, and took graduate training at the University of Chicago. In 1939 he entered practice in Memphis, and since then has been a member of the faculty of the university. Dr. Wilson entered the military service as a major with the Vanderbilt University General Hospital Unit; later, as a lieutenant colonel, he served as chief of surgery of an overseas hospital in the Mediterranean theater of operations and was then assigned to the consultants' division there. At the time of his discharge from the army he was assigned to the Consultants' Division of the Surgeon General's Office.

WEST VIRGINIA

District Health Conferences.—The annual Northern District Health Conference sponsored by the state department of health will be held October 8 at the Fairmont Hotel, Fairmont. The Southern District Conference is scheduled for October 15, at the West Virginian Hotel, Bluefield. The two meetings will be open to the public.

Ophthalmologists' Meeting.—The fall meeting of the West Virginia Academy of Ophthalmology and Otolaryngology will be held at the Greenbrier, White Sulphur Springs, September 20-21. Dr. James A. Moore, New York, will speak on "Endaural Surgery in the Modified Radical and Radical Mastoidectomies," and Dr. Oscar B. Nugent, Chicago, on "Management of Strabismus."

Emotional Aspects of Disease.—A psychiatric seminar, sponsored by the bureau of mental hygiene of the state health department and the mental hygiene committee of the West Virginia State Medical Association, will be held at St. Mary's Hospital Nurses Home, Huntington, October 6-7. Emotional aspects of the various diseases will be stressed. Clinics on the common neurologic problems are being arranged. Guest speakers include:

- Robert H. Felix, Washington, D. C., What Mental Hygiene Program Means to West Virginia.
- Oscar C. E. Hansen-Pruss, Durham, N. C., Asthma, Bronchitis and Hay Fever: Psychological Aspects and Treatment.
- Frederick G. Dersheimer, Wilmington, Del., Emotional Factors in Industry.
- R. Finley Gayle, Richmond, Va., Modern Methods of Treatment in Mental Institutions.
- William G. Hamm, Atlanta, Ga., Psychiatric Aspects of Plastic Surgery.
- Yale D. Koskoff, Pittsburgh, Clinic on Neuropsychiatric Problems.
- Robert M. Creadick, Durham, N. C., Menstrual Disorders.
- Ray O. Noojin, Birmingham, Ala., Psychologic Factors in Common Skin Diseases.

At the round table luncheon Wednesday on "The Use of Community Resources in the Handling of the Psychiatric Office Patient," Dr. Theron S. Hill, Memphis, Tenn., will speak. Guest speaker at the Wednesday reception and dinner will be Dr. C. Charles Burlingame, Hartford, Conn.

HAWAII

Mainland Visitors.—Dr. George P. Guibor, Chicago, arrived in Honolulu August 15 to give an advanced course in eye surgery with special reference to the treatment of muscle defects. Chauncey D. Leake, Ph.D., vice president of the University of Texas and dean of the university's medical school, Galveston, spoke before public meetings on September 7 and 8 in Honolulu.

Pacific Surgeons' Meeting.—Over one hundred surgeons representing every field of surgery gathered in Honolulu at Queens Hospital and the Mabel Smyth Building for the Fourth Congress of the Pan-Pacific Surgical Association, August 30-September 13. This is the first meeting of the organization since 1939 and is the largest held since the association was founded in 1929 under the auspices of the Pan-Pacific Union. The officers of the 1948 Pan-Pacific Surgical Conference are Dr. Frederick L. Reichert, San Francisco, president, and Dr. Forrest J. Pinkerton, Honolulu, Hawaii, secretary-treasurer.

GENERAL

Announce Essay Prize.—The South Atlantic Association of Obstetricians and Gynecologists announces the establishment of the Foundation Prize. Authors on papers on obstetric or gynecologic subjects desiring to compete for the prize may obtain information from Dr. Emmett D. Colvin, Secretary-Treasurer, 1259 Clifton Road, N.E., Atlanta, Ga.

Cancer Fund.—Establishment of the Babe Ruth Cancer Fund with the contribution of \$100,000 by the Revere Camera Company of Chicago has been made with the American Cancer Society for general research and for use at the society's discretion. Arrangements are being made to present the check for \$100,000 to the American Cancer Society in New York.

Tropical Medicine Awards.—At the Fourth International Congress on Malaria, Colonel Henry E. Shortt, London School of Hygiene and Tropical Medicine, was awarded the Lavan Priz for his paper "The Pre-Erythrocytic Cycle of Plasmodium cynomolgi." The Walter Reed Medal was presented to Dr. Nicolaas H. Swellengrebel, Amsterdam, Netherlands, for his researches in the field of tropical medicine, particularly in the epidemiology and control of malaria.

Kilmer Prize Award.—A system for identifying drugs from the botanical world by their fluorescent glow when exposed to invisible, near ultraviolet rays has gained the Kilmer Prize for Charles R. Chase, Jr., of Stockton, Calif. Mr. Chase was presented with an inscribed gold key by the American Pharmaceutical Association at its national convention in San Francisco last month. Mr. Chase conducted his research while a student at the University of California College of Pharmacy, San Francisco.

Society Elections.—Recently elected officers of the National Federation of Obstetric-Gynecologic Societies include: Dr. Ralph E. Campbell, Madison, Wis., president; Dr. Edward C. Hughes, Syracuse, N. Y., president elect; Dr. Woodard D. Beacham, New Orleans, secretary, and Dr. Richard Paddock, St. Louis, treasurer. At the annual meeting of the American Association of the History of Medicine in Philadelphia, in May, Dr. Henry R. Viets, Boston, was elected president, and Dr. Benjamin Spector, Boston, secretary. The American Medical Women's Association recently installed Dr. Elsie S. L'Esperance, New York, as president, and chose Dr. Dorothy W. Atkinson, San Francisco, as president elect; Dr. Isabel M. Scharnagel, New York, corresponding secretary, and Dr. Mary R. Noble, Bowmansdale, Pa., treasurer.

Reprints on the Lead Problem.—The Lead Industries Association, New York, has published a booklet combining reprints of three papers on the important aspects of health control in industrial lead workers. Dr. William C. Wilentz, medical director, Perth Amboy, N. J., Plant, National Lead Company, discusses the employer, employee and community factors of the problem. Dr. Lloyd E. Hamlin, medical director, and Herbert J. Weber, industrial hygienist, American Brake Shoe Company, Chicago, discuss the medical and engineering aspects of prevention of lead intoxication among brass foundry workers. Copies may be obtained from the Lead Industries Association, 420 Lexington Avenue, New York 17, at 50 cents each.

Fellowship Awards.—Three fellowships in medical research have been announced by the John Simon Guggenheim Memorial Foundation. The recipients are: Dr. Henry Shepard Fuller, assistant professor of preventive medicine, Bowman Gray School of Medicine, Winston-Salem, N. C.; studies of the taxonomy and distribution of mites, in relation to their transmission of diseases; Dr. James Mather Sprague, assistant professor of anatomy, Johns Hopkins University School of Medicine, Baltimore;

studies of the anatomic organization of the spinal motor system, and Dr. Doris Hawkins Phelps, research associate in obstetrics and gynecology, Vanderbilt University School of Medicine, Nashville, Tenn.: studies in reproductive and gynecologic physiology. Dr. Phelps will work at the University of Witwatersrand, Johannesburg, South Africa. The awards are a part of the twenty-fourth annual series of fellowship awards made by the foundation, established in 1925 by the late U. S. Senator Simon Guggenheim and his wife as a memorial to their son.

Subcommittee on Oncology.—The committee on pathology of the National Research Council has appointed the following subcommittee on oncology: Dr. Shields Warren, Boston, chairman; Dr. Balduin Lucké, Philadelphia; Dr. Fred W. Stewart, New York; Dr. Harold L. Stewart, Bethesda, Md.; Dr. Arthur P. Stout, New York; Dr. Milton C. Winternitz, New Haven, Conn., and Dr. Howard T. Karsner, Cleveland, chairman of committee on pathology, ex officio. Brig. Gen. Raymond O. Dart, director of the Army Institute of Pathology, is cooperating with the committee, making the institute's facilities and resources available and providing office space for the permanent secretary. The objectives of the subcommittee are: (1) improvement in the teaching of oncology; (2) dissemination of information on oncology; (3) establishment of criteria for diagnosis of tumors, and (4) simplification of terminology by recommending a single term for each tumor and listing separately the appropriate synonyms.

End Pollution of Ohio Watershed.—After thirteen years of negotiations, governors of seven states and a representative of another on June 30 signed a compact establishing a joint authority to prevent pollution of streams of the Ohio river valley. The action is intended to bring purer water to some 20,000,000 persons in a 200,000 square mile area in Indiana, West Virginia, Ohio, New York, Illinois, Kentucky, Pennsylvania and Virginia. Sewage disposal plants will be the main agency used. A compact commission, consisting of three commissioners from each state and three representing the federal government, will draft plans for administering the agreement. The lately enacted Barkley-Taft antistream pollution measure will provide for construction of a stream sanitation laboratory in Cincinnati to cost \$4,000,000 and \$20,000,000 for loans to communities for establishment of sewage disposal plants.

Baruch Committee Report.—The annual report of the Baruch Committee on Physical Medicine states that about 150 communities in the nation have or are planning civilian rehabilitation programs, as compared with a few limited facilities in physical medicine and medical rehabilitation prior to the war, and that from five approved residencies or fellowships in physical medicine available annually in three medical centers, the number has grown to seventy such residencies and fellowships now available in thirty-four medical centers. Compared to thirty medical schools then offering instruction in physical medicine, there are now sixty. Since the establishment of the committee physical medicine has become the sixteenth officially recognized medical specialty. Of the original allocation of \$1,250,000, sums totaling \$900,000 were given to Columbia University, New York University and the Medical College of Virginia, Richmond, to establish centers for physical medicine and rehabilitation. The three centers, which are being developed over a ten year period, are designed to serve as models for medical schools and hospitals. Research and training projects are also being conducted under committee grants. In addition to financial support for research and training, the Baruch Committee furnishes professional consultation and advice to the universities participating in its program through its Scientific Advisory Committee, consisting of Drs. Frank H. Krusen, Rochester, Minn., chairman; John Stanley Coulter, Chicago; John F. Fulton, New Haven, Conn.; Charles G. Heyd, New York; Andrew C. Ivy, Chicago; William S. Tillet, New York; Frank R. Ober, Boston; Winfred Overholser, Washington, D. C.; Francis O. Schmitt, Ph.D., Cambridge, Mass., and Chauncey D. Leake, Ph.D., Galveston, Texas.

MEXICO

Model Health Center.—The Institute of Inter-American Affairs has signed an agreement with the Ministry of Health in Mexico to construct a model health center in Mexico City, located in one of the poorest and most densely populated parts of the city. The health center will provide services for half of the district's population: clinics for venereal diseases, tuberculosis, acute communicable diseases, maternal and infant hygiene, mental and dental hygiene, a laboratory and facilities for health education, sanitary engineering and inspection, and a milk distribution center. Ample waiting rooms will be provided, and space will be furnished for the library and classrooms for teaching.

LATIN AMERICA

Vaccination Requirements for Persons Leaving Colombia.—All persons departing from Colombia, South America, must possess a medical certificate stating they have no infectious or contagious diseases and have also certificates of vaccination against smallpox and yellow fever. According to a resolution issued May 28, 1948, by the Minister of Health, the latter certificates must be issued by an official entity; this has been interpreted to mean that vaccination certificates are acceptable when issued by the Colombian Ministry of Health or by national public health services of other countries on Pan American Sanitary Bureau forms. Certificates issued by private physicians or clinics in Colombia or elsewhere are not acceptable. Americans traveling to Colombia may avoid revaccination and delay if they secure acceptable vaccination certificates in the United States. Colombia also requires that persons departing from that country bear official certificates of vaccination against typhoid "in the event of typhoid fever and whenever the situation warrants."

FOREIGN

Gift of Electron Microscope to Norway.—The Institute of Bacteriology of the University of Oslo, Norway, has received an RCA electron microscope as a gift from Erling H. Samuelsen, Norwegian shipowner. The instrument is Norway's first electron microscope and will be applied to research in the different virus infections in Norway. The Institute of Bacteriology, a branch of the government-operated University of Oslo, was founded ten years ago with funds provided by Kaptein W. Wilhelmsen, also a shipowner. Its work is directed mainly toward instruction of medical students and research in bacteriology and serology.

CORRECTION

Hospital Research Committee.—In the June 19, 1948 issue of THE JOURNAL, p. 710, Dr. John Homans, Boston, was incorrectly named as a member of the scientific advisory committee of The Massachusetts General Hospital.

Western Electric Hearing Aids.—The report entitled "Western Electric Hearing Aids, Models 65 and 66, Acceptable" appeared in the June 5 issue of THE JOURNAL (137:534). Inadvertently the thickness of Model 66 was recorded as 3.8 cm. (1½ inches), whereas it should have been 2.8 cm. (1¼ inches).

Marriages

JOSEPH GEORGE FUREY III, West Orange, N. J., to Miss Loretta Louise Boyan of Englewood, June 12.

LEE FREDERICK VOSBURGH, Passaic, N. J., to Miss Millicent Louise Gordon of Albany, N. Y., June 5.

DAVID SANDERS HOWELL, Boothbay Harbor, Maine, to Miss Margaret Blue of Miami, Fla., June 5.

THOMAS WOODWARD HUTSON JR., to Miss Patricia Ruth Weiland, both of Miami, Fla., in June.

BERTRAM E. SPROFEN, Paterson, N. J., to Miss Millie Small of Conway Springs, Kan., June 11.

JAMES KNIGHT QUIGLEY to Miss Florence Theresa Pocock, both of Rochester, N. Y., July 7.

LILLIAN IRENE MCCAIN to Mr. Daniel Miles McFarland, both of Southern Pines, N. C., June 9.

WILLIAM CLAYTON ROBERTSON to Miss Gloria Hoover Tyler, both of Richmond, Va., June 12.

CHARLES G. ADSIT JR., New York, to Miss Mary Priscilla Amberson of Riverdale, June 12.

NEIL CALLAHAN, Vicksburg, Miss., to Miss Frances Estelle Wilson of Norfolk, Va., June 5.

JAMES KENT RHODES, Raleigh, N. C., to Miss Helen Sara Havnaer of Hickory, June 12.

ROBERT EDWARD DAVIS, Brooklyn, to Miss Harriette Woronow of New York, July 11.

RICHARD P. GLOVE, Cleveland, to Miss Lois Lucille Yost at Wooster, Ohio, July 10.

RICHARD THOMAS JAMES to Miss Georgia C. Graham, both of Atlanta, June 5.

JAMES ALLEN, Florence, S. C., to Miss L. Johnson of Marion, June 5.

Deaths

Gilbert Christian Anderson, New Orleans; born in Jackson, Tenn., Dec. 11, 1885; Columbia University College of Physicians and Surgeons, New York, 1917; clinical professor of surgery at Louisiana State University School of Medicine; formerly instructor in neurosurgery at Tulane University of Louisiana School of Medicine; co-founder and first president of the New Orleans Society for Neurology and Psychiatry; past president of the Louisiana State Medical Society and the Orleans Parish Medical Society; member of the American Medical Association, Southeastern Surgical Congress, National Gastroenterological Association, Southern Psychiatric Association and the Central Neuropsychiatric Association; member of the founders' group of the American Board of Surgery; specialist certified by the American Board of Neurological Surgery; fellow of the American College of Surgeons; served during World War I; at one time on the staff of the Mayo Clinic, Rochester, Minn.; neurologic surgeon at the Charity Hospital of Louisiana, where he was president of the medical staff, Southern Baptist Hospital, Hôtel Dieu, French Hospital, Eye, Ear, Nose and Throat Hospital, Flint Goodridge Hospital of Dillard University, Touro Infirmary and the U. S. Marine Hospital; consulting neurologic surgeon, Gulf, Mobile and Ohio Railroad; died June 27, aged 63, of cerebral arteriosclerosis.

William Thomas Corlett, Cleveland; born in Orange, Ohio, April 15, 1854; University of Wooster Medical Department, Cleveland, 1877; L.R.C.P., London, 1881; professor emeritus of dermatology at the Western Reserve University School of Medicine; specialist certified by the American Board of Dermatology and Syphilology; a founder and past president of the Cleveland Medical Library Association; in 1937 furnished and endowed a room in the Cleveland Medical Library dedicated to research in dermatology and syphilology; past president of the American Dermatological Association; in 1883 he was elected to the Cleveland Board of Health and was active in the development of health program for public schools in Cleveland; member of the American Medical Association and in 1902 member of its House of Delegates; founder of the department of syphilology and dermatology at Lakeside Hospital; served as consulting dermatologist to the City, St. Alexis and Babies and Childrens hospitals; in 1943 received an honorary doctorate of humanities from Western Reserve University; author of "Medicine-Man of the American Indian and His Cultural Background" and other books; died June 11, aged 94, of cerebral thrombosis.

William Van Pelt Garretson ☉ New York; born in Jersey City, N. J., March 2, 1880; Columbia University College of Physicians and Surgeons, New York, 1903; formerly clinical professor of neurology at the New York Polyclinic Medical School and Hospital; specialist certified by the American Board of Psychiatry and Neurology; a member of the medical board and advisory committee on neurology and psychiatry at Doctors Hospital; served as neuropsychiatrist at Vanderbilt Clinic and consulting neuropsychiatrist at Flower and Fifth Avenue Hospitals and Reconstruction Hospital; consulting neuropsychiatrist at the Bayonne (N. J.) Hospital, Lawrence Hospital in Bronxville, N. Y., New York State Reconstruction Home, West Haverstraw, Manhattan State Hospital and Harlem Hospital; consulting neuropsychiatrist and endocrinologist at St. Clare's Hospital, where he died June 5, aged 68.

James LeRoy Campbell ☉ Atlanta, Ga.; born in Hopewell, Ga., July 15, 1870; Atlanta Medical College, 1893; emeritus professor of clinical surgery at the Emory University School of Medicine; past president of the Fulton County Medical Society; member of the founders' group of the American Board of Surgery; fellow of the American College of Surgeons; served on the staffs of the Emory University and Grady Memorial hospitals; director of the Sheffield Cancer Clinic, Georgia Baptist Hospital; in 1937 his name was inscribed on the L. G. Hardman Loving Cup, awarded annually to the physician considered to have rendered the most distinguished medical service during the previous year; for many years chairman of the Georgia executive committee of the Georgia division of the Field Army of the American Cancer Society; from 1939 to 1946 member of the board of directors of the American Cancer Society; died June 11, aged 77, of coronary thrombosis.

James Stewart ☉ Jefferson City, Mo.; born in Glasgow, Scotland, Sept. 22, 1874; Barnes Medical College, St. Louis, 1895; at one time practiced in Holstein, Mo., where he served as coroner of Warren County and as local surgeon for the Missouri, Kansas and Texas Railroad; formerly associated with the U. S. Public Health Service; serving as secretary of the

state board of health and as state health commissioner; in 1929 established what is now the bureau of vital statistics of Missouri; formerly director of the hygiene division of the public school system in St. Louis; formerly member of the state legislature; an Affiliate Fellow of the American Medical Association; member of the American Public Health Association, Missouri Crippled Children's Society and the Missouri State Tuberculosis Association, of which he had been president; served as a member of the city chamber of commerce; on the staff of St. Mary's Hospital, where he died May 18, aged 73, of cerebral hemorrhage.

Frank Vero ☉ New York; born in Czechoslovakia in 1897; Univerzita Komenského Fakulta Lekarská, Bratislava, Czechoslovakia, 1922; professor of dermatology and syphilology at the New York Polyclinic Medical School and Hospital; instructor in dermatology at the Columbia University College of Physicians and Surgeons; member of the American Academy of Dermatology and Syphilology; specialist certified by the American Board of Dermatology and Syphilology; formerly secretary of section on dermatology and syphilology of the New York Academy of Medicine; assistant visiting dermatologist at the Lincoln Hospital; attending dermatologist and syphilologist to the New York Polyclinic Medical School and Hospital, Presbyterian Hospital and Vanderbilt Clinic; died May 18, aged 50.

William Melville Smith ☉ Olean, N. Y.; born in Olean, N. Y., Dec. 20, 1900; University of Buffalo School of Medicine, 1924; fellow of the American Public Health Association; for many years coroner of Cattaraugus County; from 1937 to 1942 assistant district state health officer in New York state; major in the medical corps, Army of the United States, serving in England during World War II; formerly director of preventable diseases, North Dakota State Department of Health in Bismarck, and acting state health officer; served on the faculty of St. Bonaventure (N. Y.) College and as consultant on the staff of the Edward J. Meyer Memorial Hospital in Buffalo; died May 29, aged 47, of coronary thrombosis.

Charles Henry Young, La Porte, Texas; born in Everett, Mass., March 22, 1876; Tufts College Medical School, Boston, 1905; chief of hospitalization for the U. S. Army in England during World War I; formerly superintendent of the Presbyterian Hospital in New York, Hospital of the Good Shepherd in Syracuse, N. Y., Maine General Hospital, Portland, Mountinside Hospital, Montclair, and Stamford Hospital in Stamford, Conn.; at one time temporary superintendent of the Jefferson Hospital in Birmingham, Ala., and associate professor of hospital administration at the Syracuse (N. Y.) University College of Medicine; died in the U. S. Naval Hospital, Houston, Texas, May 22, aged 72.

Louis Albert Thomas, Red Oak, Iowa; born in 1862 (licensed in Iowa in 1893); member of the American Medical Association; formerly secretary of the state board of health, secretary of the state board of medical examiners and state registrar of vital statistics; for many years health officer and medical inspector of schools for the city of Red Oak; charter member of the board of directors of the Montgomery County Chapter of the American Red Cross, serving as executive secretary for many years; affiliated with the Murphy Memorial Hospital, where he died May 26, aged 86, of carcinoma of the colon.

John George Abbott, West Hollywood, Calif.; Jefferson Medical College of Philadelphia, 1905; died May 22, aged 69, of bronchopneumonia.

Elmer E. Allenbaugh, Dale, Ind.; Cincinnati College of Medicine and Surgery, 1888; died June 6, aged 87, of myocarditis.

Gabriele Ariola, Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1915; died in Hollywood, Fla., June 7, aged 71, of pneumonia.

Alonzo Eugene Austin, New York; New York Homeopathic Medical College and Hospital, New York, 1897; formerly on the faculty of his alma mater; died in the Flower and Fifth Avenue Hospitals, June 20, aged 79, of cerebral arteriosclerosis.

William Emerson Barnes, Evansville, Ind.; Indiana University School of Medicine, Indianapolis, 1916; served during World War I; for many years connected with the county board of health; past president of the staff of Deaconess Hospital; died in McFarland Hospital, Lebanon, Tenn., May 23, aged 56, of cerebral hemorrhage.

Ernest Edward Bishop ☉ Cincinnati; University of Cincinnati College of Medicine, 1919; tuberculosis coordinator of Hamilton County since 1941; member of the American Trudeau Society; instructor in medicine at his alma mater; formerly superintendent of the Hamilton County Tuberculosis Sanatorium; on the staff of the Cincinnati General Hospital; died June 13, aged 53, of coronary occlusion.

Joseph Bixby * Geneva, Neb.; University Medical College of Kansas City, Mo., 1900; past president of the Nebraska State Medical Association; mayor of Geneva from 1932 to 1946; during World Wars I and II served on the advisory and examining boards of Fillmore County; affiliated with Geneva General Hospital; died in Chicago June 25, aged 72, of heart disease.

Stonewall Jackson Blackmon * Kershaw, S. C.; Jefferson Medical College of Philadelphia, 1918; died June 15, aged 55, of coronary occlusion.

Andrew Blair * Charlotte, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1924; served during World War I; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past president of the Mecklenburg County Medical Society; on the staff of Presbyterian Hospital, where he died June 3, aged 52, of coronary occlusion.

James Michael Borgia, Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1918; on the staff of the Adelphi Hospital; died June 9, aged 57, of cirrhosis of the liver.

Walter William Boyne, East St. Louis, Ill.; St. Louis University School of Medicine, 1913; formerly county coroner; served during World War I; died June 23, aged 58, of streptococcal endocarditis.

James Richard Brandon, Canton, Ohio; Ohio State University College of Medicine, Columbus, 1925; specialist certified by the American Board of Otolaryngology; on the staff of the Aultman Hospital; member of the American Medical Association; died May 29, aged 51, of carcinoma of the right kidney.

William Ausborn Brewer * Cowan, Tenn.; Memphis Hospital Medical College, 1911; served overseas during World War I; died May 24, aged 65, of myelogenous leukemia and diabetes mellitus.

Elizabeth Stow Brown, New York; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1885; secretary of the Montclair (N. J.) Chapter of the American Red Cross during World War I and decorated by the French government for her services to the American Hospital in Paris; died in the New York Infirmary April 9, aged 87, of arteriosclerotic heart disease with decompensation and mesenteric thrombosis.

William R. Brumfield, Gloster, Miss.; Louisville (Ky.) Medical College, 1891; member of the American Medical Association; past president of the Amite County Medical Society; formerly member of the state legislature, board of aldermen and school board; died June 7, aged 80, of lobar pneumonia.

Harry Ralph Carroll, Cincinnati; University of Cincinnati College of Medicine, 1912; member of the American Medical Association; died at St. Mary's Hospital May 10, aged 58, of congestive heart failure and hypertension.

Roy Lewis Carter, Louisville, Ky.; Hospital College of Medicine, Louisville, 1898; county coroner; affiliated with the Kentucky Baptist and St. Anthony's hospitals; died May 10, aged 74, of coronary occlusion.

David Troy Cheairs, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1914; member of the American Medical Association; medical examiner for the Workmen's Compensation Commission; on the staffs of St. Vincent's and Baptist State hospitals; died May 28, aged 62, of coronary heart disease.

Martin Francis Crotty * Cambridge, Mass.; Boston University School of Medicine, 1924; member of the New England Obstetrical and Gynecological Society; served during World War I; affiliated with the Chester Hospital; died June 5, aged 54, of cerebral hemorrhage.

Albert Johnston Gardner, Norborne, Mo.; Washington University School of Medicine, St. Louis, 1901; city health officer; died in St. Joseph, May 4, aged 74, of cerebral hemorrhage.

Joseph Savan Gatlin * Laurel, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1912; served overseas during World War I; died June 14, aged 61, of coronary thrombosis.

Frederick William Gessner * Dysart, Iowa; Northwestern University Medical School, Chicago, 1910; past president of the Tama County Medical Society; for many years served on the board of education and as health officer; died June 7, aged 68, of coronary occlusion.

James Garfield Janney * Dodge City, Kan.; Ensworth Medical College, St. Joseph, Mo., 1910; formerly associated

with the Indian Service; served during World War I; died in De Paul Hospital, St. Louis, May 26, aged 64, of dislocation of the cervical spine with paraplegia received in an automobile accident.

George Klumpner, Ottawa, Ill.; Loyola University School of Medicine, Chicago, 1921; member of the American Medical Association; past president of the La Salle County Medical Society; served during World War I and during World War II; psychiatrist for the La Salle County draft medical advisory board; affiliated with the Ryburn-King Hospital, where he died June 1, aged 55, of coronary occlusion.

Minerva Blair Pontius * Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; died May 1, aged 77, of chronic myocarditis.

Elias Pratt, Essex, Conn.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1887; member of the American Medical Association; past president of the Connecticut State Medical Society, Connecticut Public Health Association and the Litchfield County Medical Society; for many years practiced in Torrington, where he was on the staff of the Charlotte Hungerford Hospital, city health officer and school and city physician; died May 28, aged 88, of coronary occlusion.

Alfred Skippen, Portland, Ore.; Victoria University Medical Department, Coburg, Ontario, Canada, 1892; died May 8, aged 88, of senility.

Harry Wilbur Smiley, Indio, Calif.; University of Arkansas School of Medicine, Little Rock, 1918; member of the American Medical Association; formerly associated with the Indian Service; died in the Scripps Memorial Hospital, La Jolla, April 26, aged 63, of bronchogenic carcinoma of the right lung.

James Herbert Sowerby, Bedford, Va.; Northwestern University Medical School, Chicago, 1907; died in the John Russell Hospital May 23, aged 65, of coronary occlusion.

Charles William Spragg, Waynesburg, Pa.; Jefferson Medical College of Philadelphia, 1897; member of the American Medical Association; on the staff of the Greene County Memorial Hospital; died in the Western Pennsylvania Hospital, Pittsburgh, May 4, aged 75, following a prostatectomy.

Robert Armstrong Stewart, Independence, Iowa; Jefferson Medical College of Philadelphia, 1903; member of the American Psychiatric Association and the American Medical Association; superintendent of the Independence State Hospital, where he died May 24, aged 69, of coronary thrombosis.

Samuel Stewart * Syracuse, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1906; formerly school commissioner; served overseas during World War I; on the staff of the Crouse Irving Hospital; died May 15, aged 68, of chronic nephritis and hypertension.

Troy Warren Swallum, Spencer, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1919; member of the American Medical Association; served as county coroner; died in Mercy Hospital, Iowa City, May 5, aged 57, of coronary thrombosis.

Bartholomew Phillip Sweeney * Leominster, Mass.; Baltimore Medical College, 1911; member of the American Urological Association; for many years member of the city health department; on the staff of the Leominster Hospital; died May 20, aged 61, of heart failure.

Lester James Talbot * New York; University of Pennsylvania School of Medicine, Philadelphia, 1936; assistant professor of obstetrics and gynecology at the New York University College of Medicine; served as a fellow in medicine of the National Research Council; on the staff of the Bellevue Hospital; died in the Mount Sinai Hospital June 4, aged 37, of acute staphylococcal endocarditis.

Edith Subers Thompson * Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1903; died April 15, aged 67, of hypertension and arteriosclerosis.

Frank Van Doren, Portland, Ore.; University of Pittsburgh School of Medicine, 1911; served during the Spanish-American War and World War I; died May 23, aged 68, of congestive heart failure.

Harry D. Vincent, Schenectady, N. Y.; Baltimore Medical College, 1893; died in the Glenridge Sanatorium May 7, aged 84, of tuberculosis of the lungs.

William Zimmer * Hillside, N. J.; Columbia University College of Physicians and Surgeons, New York, 1931; served during World War II; on the dispensary staff of the Elizabeth General Hospital and on the staffs of the Community Hospital, Presbyterian Hospital and the Beth Israel Hospital in Newark, where he died June 9, aged 40, of coronary disease.

The Inauguration of National Health Service

The British Medical Association has examined the question of "improper practices" alleged in Parliament by a socialist member, because some doctors refused to take certain patients on their lists for the National Health Service. The association finds that the service has started smoothly in most districts. Nevertheless, difficulties are being met with, as is inevitable with such a vast piece of social legislation. These should be neither exaggerated nor glossed over. It would be unfair to put blame on doctors for misunderstandings which are not of their making, and still more unfair to charge the entire medical profession with incorrect behavior which involves only a small minority. The British Medical Association has laid down the following points:

1. The basis of family medical practice is free choice, which works both ways. No doctor should be forced to take any particular patient, just as no person should be forced to have any particular doctor. Neither of them need give any reason for refusal.
2. The service is open to all irrespective of income. The association is confident that the profession in general would strongly deprecate the refusal of any doctor to accept a person as a National Health Service patient on financial grounds. The decision whether to be a public or private patient must be a matter for the individual.
3. Every doctor has a right to set a limit to the number of patients he is prepared to accept on his list. Within the service all receive equal treatment according to their medical needs. It is impossible for the doctor—or indeed for the government or the administration—to give any public patient advantages or privileges not enjoyed by others. It must never be overlooked that there is a grave shortage of doctors and facilities.
4. The association is confident that the profession will feel strongly that, although a doctor is fully entitled to decline work for which he has no special aptitude, it would be entirely wrong for him to discriminate against particular classes; e. g., to refuse to accept as patients children or old persons on the ground that they involve too much work. This is regarded as contrary to the standards of medical practice. It might have been added that some of the dissatisfaction expressed at the inauguration of the service is due to the exaggeration of its advantages and the ignoring of its drawbacks by the socialists, in the usual manner of politicians.

Jonathan Hutchinson as an Educationist

The recent book, "A Country Museum. The Rise and Progress of Sir Jonathan Hutchinson's Educational Museum at Haslemere," portrays this great clinician as versatile in fields outside of medicine. Hutchinson believed that museums should be teaching institutions for both natural science and human history. That exhibits should illustrate definite points, be informatively labeled and supplemented with drawings, photographs or anything else appropriate. "A museum should become a richly illustrated book. It should be a place to which teachers would take their pupils, not once a year as a holiday, but frequently, as the best method of serious study." His enthusiasm he also expressed in this outburst: "Who knows not the delights of a museum after the fatigue and disappointment of books!"

For the teaching of human history and geology he adopted what he called "a space for time method." For each subject a wall of long gallery was ruled into equal divisions, each representing a certain period, which for human history was a century; for geology so many million years. At Haslemere, his country residence near London, at his week end intervals

from professional work, he gave much time to the instruction of children and adults. He lectured on such diverse subjects as "the age of the earth," "fruits and seeds," "chalk," "Hebrew history and Fénelon." Often he would preface his lecture by remarks on objects that he had picked up on his way to the museum such as a flower or a piece of flint. Hutchinson died in 1913, and in 1926 the museum was handed over to trustees by his family.

The Haslemere Education Museum has long been a model of what the museum of a small town should be and has exerted a wide influence on other museums. It has won a unique position by a valuable system of regular lectures to organized parties of school children, of whom nearly 1,000 came in 1946. Hutchinson had no time for what the ordinary man calls amusement, but all his work, whether investigation or teaching, was for him amusement.

Penicillin and Tuberculosis

Penicillin has been considered as having no effect on the tubercle bacillus. However, P. Courmont and H. Cardere have just reported to the Society of Biology and to the Society of the Lyons Hospitals their research which proves the bacteriostatic and bactericidal (above certain doses) action in vitro of penicillin on *Mycobacterium tuberculosis*. The authors (S. Arloing and P. Courmont) used a homogenous culture of *M. tuberculosis* in a liquid medium, where they develop in three days only; the bacilli are separated one from another in this medium and in this way are better exposed to the action of the antibiotic. A series of tubes containing, with the culture bouillon, penicillin in quantities decreasing from 5,000 units to 10 units per cubic centimeter is inseminated with 40,000,000 tuberculosis bacilli and put into an incubator, together with test tubes containing no penicillin. After three days, the bacillus grows in the latter, but after six days there is no growth in the former. Cultures develop only from the seventh to the twentieth day, in inverse ratio to the quantity of penicillin added. There is no culture in the tubes containing 5,000 and 2,500 units. The antibiotic effect is much more noticeable if the quantities of penicillin destroyed at 37 C. in the tubes are replaced regularly day by day. The test tubes containing no penicillin have always given culture in three days. Acting on those researches, the authors intend using penicillin in the treatment of certain cases. The authors are also considering the use of penicillin therapy, at high doses by subcutaneous and intrarachidial route, in tuberculous meningitis, in the place of the toxic streptomycin.

New Treatment of Amebic Dysentery

Recently Lepesme reported in the *Revue de Botanique Appliquée* that *Holarrhena floribunda* (a shrub of the apocynaceous family) contains alkaloids specifically effective on dysenteric amebae and cysts. At a recent meeting of the National Academy of Medicine, Crosnier, Merle and co-workers set forth their first therapeutic results.

1. With total extract of this plant, they obtained disappearance of amebae in 9 of 13 cases of acute dysentery and failed in 4; treatment was successful in all of 6 cases of colitis with the cysts present. Those results are the more interesting because the patients had previously been treated without success with emetin.

2. The use of conessine hydrochlorate in 13 cases of acute dysentery (*Endamoeba histolytica*) was successful in 12 cases. Dosage varies according to the degree of intolerance of the subject: as a rule, 0.50 Gm. per day (0.10 Gm. tablets) is given for four to five days, and then the dose is decreased to 0.40 Gm.,

0.30 Gm., 0.20 Gm.; average total dose: 5 Gm. If there is intolerance above 0.30 Gm. per day, treatments are to be spread out over fifteen to twenty days.

The authors are of the opinion that total extracts of *Holarrhena floribunda* are as effective as acetarsone; perhaps future experience will permit one to consider it as superior to emetine.

Death of Professor Alexandre Couvelaire

A well known obstetrician, a member of the National Academy of Medicine, has died at the age of 75. He was a disciple of Adolphe Pinard, whom he succeeded. The most important among his numerous works are an anatomico-pathologic study of ectopic pregnancies and a study of uteroplacental apoplexy, which is so complete that this disease will henceforth bear his name. His "Introduction to the Study of Obstetrical Surgery" is one of the best medical books. He inaugurated at the Clinique Baudelocque the dispensary for hereditary diseases, an institution with which all maternity hospitals in France have been provided. One of his numerous disciples, Professor Levy-Solal, succeeds him at the Clinique Baudelocque.

Personals

Dr. G. Baehr, chief of the medical department at the Mount Sinai Hospital, president of the New York Academy of Medicine, was received at one of the recent meetings of the Paris National Academy of Medicine.

Dr. A. M. Pappenheimer of New York University has just delivered a lecture at the Pasteur Institute on the diphtheric toxin considered in its relations with the respiratory system.

ITALY

(From Our Regular Correspondent)

July 9, 1948.

Stenosis of the Esophagus

Reports were presented during the recent National Congress of Surgery on stenosis of the esophagus. Professor Redi reported on cicatricial stenosis and Professor Ferreri and Dr. Coppo on the diagnosis of stenosis of the esophagus by means of esophagoscopy.

Professor Redi discussed stenosis resulting from the ingestion of caustic solutions. Children have paid the largest tribute to these grave incidents. Rapid improvement after the acute incident leads the family of the victim and sometimes the physician to a fallacious optimism and to the omission of adequate prophylaxis of the future stenosis. Young persons may be saved instead of becoming unfortunate carriers of a gastric fistula, condemned to a short and unhappy existence.

With regard to therapy, the speaker distinguishes two groups of stenosis: those which may be benefited by conservative treatment based only on subsidiary surgical measures such as peroral dilation and the graver cases in which extensive surgical treatment is required to create a new way of communication between the part of the esophagus above the stricture and the stomach. The speaker discussed the complex surgical procedures which have been employed in prethoracic esophagoplasty. The results, sometimes brilliant but uncertain, have induced surgeons to study methods of improving the esophagoplasty.

Great interest was shown in the results of the Anglo-American surgeons whose methods are based on using the stomach, which is drawn into the thorax through a diaphragmatic breach until anastomosis of the fundus with a portion of the esophagus above the stenosal lesion may be accomplished. With ingenuity those anastomoses, which can be combined with resection of the diseased esophagus, may be practiced also above the arch of the aorta, thus carrying the stomach almost to the superior orifice of the thorax. The results were entirely satisfactory. Professor Redi predicted

the use by Italian surgeons of these definitely promising procedures.

In the second part of the report Professor Ferreri and Dr. Coppo furnished evidence of the importance of endoscopy in diagnosis. Esophagoscopy deserves to become the common procedure in all patients who have disturbances of the esophagus. Dysphagia and hematemesis are the main symptoms which require esophagoscopy. Aneurysm, advanced cachexia, severe diabetes and hyperazotemia are to be considered as contraindications to endoscopic examination.

With regard to anesthesia the speakers recommended limiting general anesthesia to the cases of intractable children or cases in which it may be a means of relieving a spastic condition of the esophagus. In other cases local anesthesia, as a rule, is recommended and it may be preceded by basal anesthesia. In young infants and in old persons one may use either one of the types of anesthesia.

Among the contributions presented on this subject, Professor Broglio of Belluno discussed two methods of esophagoplasty most frequently employed, that of Lexer (jejunodermoesophagostomy) and that of Wullstein (colonodermoesophagostomy). He reported 3 patients with insurmountable stenosis of the esophagus after the ingestion of caustics, operated on with favorable results. One of them submitted to twenty-four interventions before he recovered. The speaker also discussed the modifications of the technic which he had applied to the original surgical methods.

In the discussion Professor Dogliotti, of the University of Turin, emphasized the excellent results obtained by Broglio, but pointed out the difficulties in doing prethoracic plastic operations; he insisted that one should practice dilation as soon as possible.

At the end of the discussion Professor Redi emphasized that concerning the lower third of the esophagus many surgeons agree to institute the new intrathoracic surgery, while concerning the median and upper thirds many authors have a reserved attitude. It is important to note that this surgery requires a complete and suitable instrumentation.

Meeting of Dr. Pappenheimer (New York) and Dr. Holt (London) in Naples

An interesting scientific meeting took place between Dr. A. M. Pappenheimer from the University College in New York and Dr. L. B. Holt, director, Department for Toxins and Antitoxins, Wright Institute, London, at the Italian Scientific Institute and in the presence of many authorities of various universities. Present were many Italian scientists and many from abroad. Dr. Pappenheimer discussed his research on the allergic reactions to diphtheric antigens which are an obstacle to the extensive vaccination of adults. The importance of the problem has grown with the increased incidence of diphtheria in many countries. Dr. Pappenheimer demonstrated that the allergic reactivity is the highest in Schick-negative persons. Based on these results experiments of vaccination were initiated in adults in New York. Dr. Holt, Professor Carlinfanti and Professor Zironi participated in the discussion.

Conferences Held by Drs. Kessler and Weintrob

Contemporaneously there have been held two important conferences by Drs. Kessler and Weintrob in the rooms of the United States Information Service. The conference of Dr. Kessler dealt with the rehabilitation of amputees. An interesting motion picture in colors was shown on the same subject. In addition to its technical value, this conference brought forth statements of sociophilosophic character of great importance. Dr. Kessler is going to Greece for additional conferences, having been invited by the Greek Government. Dr. Weintrob also was successful with his subject, Surgical Lessons of World War II.

Correspondence

RADON TREATMENT OF CANCER OF THE BLADDER

To the Editor:—Dr. Benjamin S. Barringer in the discussion of his paper, "Twenty-Five Years of Radon Treatment of Cancer of the Bladder" in *THE JOURNAL* (135:616-618 [Nov. 8] 1947), questioned many features of an article of mine, "A Comparison of Radiation and Surgery for Cancer of the Bladder," (*J. A. M. A.* 134:501-507 [June 7] 1947). He concluded, "I doubt the accuracy of his published results."

Dr. Barringer may interpret the figures as he sees fit, but the accuracy of them has been substantiated by an independent observer. This substantiating study has been recently published as a part of an editorial comment in the abstract section of the new journal *Cancer*.

Radiation of vesical cancer is a widely accepted method of therapy, so that the accuracy of published results obtained in 300 consecutive cases which were treated during a time of great enthusiasm should be important to all those dealing with this disease. Dr. Barringer's remarks had increased the therapeutic confusion particularly by doubting the principal basis of my article, the statistics.

VICTOR F. MARSHALL, M.D., New York.

TREATMENT OF MENINGITIS

To the Editor:—I have read with interest the letter from Dr. David Lehr which appeared in *THE JOURNAL* July 24, page 1150.

Most of the apparent differences between Dr. Lehr's results and ours are due to different objectives and a difference in the methods used. We were attempting to determine whether a larger dose of sulfonamide compounds than is customarily used would lower the fatality rate in meningitis, and we employed the sulfadiazine-sulfamerazine combination in the hope that it would prevent the increase in renal calculi which might otherwise result from the increased dose, or better still, might lower the incidence of renal calculi in spite of the increased dose. Our paper reported the results obtained with this higher dose.

We agree that it would be unfortunate if anyone should misconstrue our report to mean that, if similar doses of sulfonamide compounds were employed, the incidence of calculi would not be less in the patients receiving the sulfonamide compounds than in those receiving a single sulfonamide compound.

The proportion of patients who received sulfonamide drug intravenously was no different in our two series. The same clinicians were responsible for the treatment in both instances and the same criteria were employed to select those patients who were to receive the sulfonamide compounds by the intravenous route. There were no instances in either series in which conjunctivitis occurred alone. Whenever conjunctivitis was attributed to hypersensitivity to sulfonamide drug, it occurred along with a sulfonamide rash.

The one real difference in our findings is the increased incidence of sensitization when two drugs are used compared to one drug alone. This may have been due to the differences in total dosage employed in our two series, but the evidence (cited in our discussion) which we had previously obtained when we used sulfadiazine-sulfathiazole mixtures in pneumonia is against this conclusion. Theoretic reasons might be advanced in favor of either possibility; that is, either an increase or a decrease in the incidence of sensitization when a combination of drugs is used. Accordingly, the only way to deter-

mine which point of view is correct is to carry out controlled studies in several centers in which such a comparison is made, using the identical total dosage in each instance. We hope that such studies will be undertaken. Regardless of the results of these studies, however, we feel that the conclusion in our original article is still valid; namely, "that in the doses employed for the treatment of meningococcic meningitis the disadvantages of using a mixture of sulfadiazine and sulfamerazine outweigh the advantages."

HARRY F. DOWLING, M.D., Washington, D. C.

Medical Motion Pictures

FILM REVIEWS

Some Aspects of Clinical Endocrinology. 16 mm., black and white, silent, 1,175 feet (4 reels), showing time forty-nine minutes (sound speed). Prepared in 1936 by Lewis M. Hurxthal, M.D., Medical, Surgical and Neurosurgical Departments of Lahey Clinic, Boston, Mass. Produced by and procurable on loan from: Worcester Film Corporation, 131 Central Street, Worcester, Mass.

This film is a review of each gland of internal secretion with a fairly successful attempt to show a patient with the diseases due to overactivity or underactivity of each gland. It contains an excellent collection of cases and, since the appearance of the patients with these diseases does not alter through the passage of the years and since the authors confined themselves to basic facts which also have not changed, the film is just as accurate now as when printed. The "split frame" technic of showing patients "before and after" is well done.

If the film were in color and the photography of more recent perfection, it would still probably be the best in its field. As it is, the lack of color and the "flicker" would almost immediately impress an audience with its antiquity, and the audience would lose interest in what was being presented regardless of its perennial soundness. This production is suitable for showing to practicing physicians, medical students and nurses.

The School That Learned to Eat. 16 mm., color, sound, 800 feet (1 reel), showing time twenty-five minutes. Prepared in 1948 by the University of Georgia, School of Education, Athens, and sponsored by General Mills, Inc., Minneapolis. Produced by Southern Educational Film Production Service. Procurable on loan from: General Mills, Inc., 400 Second Avenue, South, Minneapolis 1.

The film tells the story of how a small village in Georgia improved the health of its children and a whole community. The health situation in their village was studied. One of the important factors found which contributed to poor health related to poor eating habits, and the film shows how the community improved its health by improving its eating practices. The solution was worked out by using old as well as new and ingenious devices. It is an interesting story for adults and teachers and could be understood and enjoyed by children. The color photography is excellent.

Coarctation of the Aorta. 16 mm., color, sound, 900 feet (1 reel), showing time twenty-seven minutes. Prepared in 1948 by John C. Jones, M.D., Thoracic Surgery Department, Children's Hospital, Los Angeles, Calif. Produced by Billy Burke, Hollywood, Calif. Procurable on loan from the author, 1136 West Sixth Street, Los Angeles 14.

This film briefly reviews the embryology, anatomy and physiology of coarctation of the aorta, outlines the clinical features and roentgen findings, then explains the surgical treatment. Resection of a coarctation with end to end anastomosis is illustrated, then followed by roentgenograms and the presentation of the patient three months postoperatively. The anatomy and physiology and the operation are clearly shown. This production shows evidence of advance planning. It is well organized, the color photography is excellent, and it is recommended as a teaching film for medical students; also for surgeons who wish to review the surgery of coarctation of the aorta.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I & II.* Various Centers, Feb., June, and Sept., 1949. *Part II.* April, 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa. *Part III.* Boston and New York, Autumn. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written.* Various Centers, Jan. 21, 1949. Final date for filing application is Oct. 1. *Oral.* Philadelphia, Oct. 10. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Oct. 18. *Oral.* Chicago, Oct. 13-15; Philadelphia, Nov. 3-5; San Francisco, date not set. Candidates not taking these special oral examinations will have no opportunity for admission next year. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part I.* Various Centers, Feb. 4, 1949. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 1.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral.* Chicago, Oct. 6. *Written.* Various Centers, January 1949. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPEDIC SURGERY: *Part I.* Various Centers, April & May. Final date for filing application is Dec. 31. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral.* Chicago, Oct. 5-8. New York City, Spring, 1949. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PATHOLOGY: Chicago, Oct. 8-9. Final date for filing application is Oct. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

AMERICAN BOARD OF PEDIATRICS: *Oral.* Seattle, Sept. 10-12. Atlantic City, Nov. 17-19. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines, Iowa.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

AMERICAN BOARD OF PSYCHIATRY & NEUROLOGY: New York City, Dec. 13-15. Final date for filing application is Sept. 15. Sec., Dr. F. J. Braceland, 102-110 2nd Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written.* Various Centers, March 1949. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 28-30, 1949. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

ARKANSAS: * *Little Rock*, Nov. 4-5. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic Examination.* Little Rock, Nov. 4. Sec., Dr. C. H. Young, 1415 Main St. Little Rock.

CALIFORNIA: *Oral.* Los Angeles, Nov. 20-21. *Written.* Sacramento, Oct. 18-21. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

COLORADO: * *Endorsement.* Denver, Oct. 5. Final date for filing application is Sept. 18. Sec.-Treas., Dr. Walter W. King, 831 Republic Bldg., Denver 2.

CONNECTICUT: * *Examination.* Hartford, Nov. 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic Examination.* Derby, Nov. 9-10. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA: * *Reciprocity.* Washington, Sept. 13. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

GEORGIA: *Examination.* Atlanta, Oct. 12-13. *Endorsement.* Atlanta, Oct. 14. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

GUAM: *Endorsement.* Agaña, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

ILLINOIS: Chicago, Oct. 5-7. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

INDIANA: *Examination.* Indianapolis, June 1949. Sec., Board of Medical Registration & Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

IOWA: * *Examination.* Des Moines, Dec. 6-8. *Endorsement.* Des Moines, Oct. 4. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

KANSAS: Topeka, Dec. 15-16. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: *Examination.* Louisville, Dec. 13-15. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

LOUISIANA: *Examination.* New Orleans, Dec. Sec.-Treas., Dr. R. B. Harrison, 1507 Hilernia Bank Bldg., New Orleans 12. *Homeopathic Examination.* Baton Rouge, subject to call. Sec., Dr. F. H. Hardenstein, 715 Peré Marquette Bldg., New Orleans.

MAINE: Portland, Nov. 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Examination.* Baltimore, Dec. 14-17. *Endorsement.* At the discretion of the Board. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, Dec. 7-8. Sec., A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: *Examination.* Boston, Nov. 16-19. Sec., Board of Registration in Medicine, Dr. G. L. Schadt, 413 E. State House, Boston.

MICHIGAN: * *Examination.* Lansing, Oct. 13-15. *Endorsement.* Oct. 12. Sec., Dr. J. E. McIntyre, 203 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, Oct. 19-21. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSOURI: St. Louis, Oct. 25-27. Exec. Sec., Mr. John A. Hailey, P.O. Box 4, Jefferson City, Mo.

MONTANA: Helena, Oct. 4-6. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEVADA: Carson City, Nov. 1. Sec., Dr. G. H. Ross, Industrial Bldg., Carson City.

Medical Economics

GERMAN EXPERIENCE WITH SOCIAL INSURANCE

F. G. Dickinson, Ph.D., Director, Bureau of Medical Economic Research

NOTE: This summary of an important study of interest to physicians has been prepared without critical comment on the author's materials, data and interpretations; it is merely a summary.—ED.

Social Security measures in the United States have not yet been tested under adverse economic conditions; Germany has operated state-sponsored welfare programs for over half a century. Dr. Sulzbach¹ reviews the history of German social insurance in order that America may foresee the economic and psychologic problems which she will face in the future.

The concept of compulsory social insurance was introduced in Germany by Chancellor Bismarck in 1881, in order to win over the laboring class by offering a form of government assistance more dignified than relief. Because employers were required to pay a part of the premiums, the programs were enthusiastically received by the workers and grew until the 1932 depression revealed their basic flaws. The several schemes were never integrated into an over-all system; each operated under a different plan and a separate administration. Each, with the exception of unemployment insurance, started from a small beginning and expanded to include additional benefits and wider occupational and income groups.

GERMAN HEALTH INSURANCE

The sickness insurance act, introduced in 1883, was the first of the German compulsory social insurance programs. Autonomous local funds, organized along occupational lines, collected premiums and distributed benefits. Rates were set at 1½ per cent of wages, two thirds to be paid by the insured and one third by the employer. Statutory benefits consisted of free medical care for thirteen weeks and a cash benefit amounting to 50 per cent of the local wage rate paid from the fourth day of illness. Inclusion of additional benefits and rapid expansion of coverage led to the breakdown of the system in the depression. It was not until Hitler came to power that artificial stimulation of the German economy put the program on its feet again.

Cost of Administration.—Cost of administering the German health insurance program is estimated at 9.6 per cent of total expenditure in 1914, and 6.8 per cent in 1925. These figures do not include bookkeeping costs of employers and legal and postal services performed free of charge by the government. Perhaps a more accurate picture is given by the fact that four fund workers were employed for every three insurance doctors.

The Problem of Malingering.—Under German health insurance, the duration of illness increased progressively from 14.1 days per illness in 1885 to 29.3 days per illness in 1932. The latter figure is 70 per cent higher than in the United States. Supervising physicians, appointed to curb abuses, found up to 50 per cent of the persons on sick lists able to work. During the depression, an emergency measure required the payment of a small fee for medical services and prescriptions; insurance claims promptly dropped more than 50 per cent in many companies. The principle of risk sharing, recognized by other health insurance countries, seems to be the only effective way to check malingering.

The Medical Profession Under Health Insurance.—At its outset in Germany, health insurance was not socialized medicine and was not opposed by the medical profession. Prior to 1913, the funds hired a limited number of physicians and the insured had no choice of doctors. Protests by the members of the profession led to an agreement in 1913 providing for contract committees representing physicians and the funds and for free

choice of physicians on the fund roster. Payment was on a capitation basis. By 1928, 80 per cent of German doctors were participating in the system and their pay, averaging \$2,620 annually, constituted 60 per cent of all medical earnings. The ratio of physicians to insured persons was 1 to 1,350.

The achievements of the German health insurance program are difficult to estimate. Infant mortality and death rates declined no faster in health insurance countries than in countries without such programs. The deficiencies of the system are far more apparent, and are instructive to American social planners. Supervising physicians had to be withdrawn from practice in order to prevent abuses. Malingering made premiums excessively high and reduced production by increasing unnecessary absenteeism. Risk sharing was necessary, but extremely unpopular. The incidence of the premium paid by the employer fell on the worker in the form of lower wages or decreased employment; thus the entire cost of the program was actually borne by the insured.

ACCIDENT INSURANCE

Accident insurance is more widespread than any other form of social insurance. Germany set the pace in 1884, with a system in which occupational associations paid the entire contribution for manual laborers in their fields. Premiums were determined by the size of payrolls and the risks involved in each occupation. Benefits included medical treatment, funeral benefits and survivors' pensions, and pensions for total or partial incapacity. By 1928, sixty-six occupational groups were covered. Expansion of benefits and coverage continued until the depression forced a reduction in employers' contributions. The accident insurance program was continued and strengthened under Hitler, who found, as had Bismarck half a century before, that the German people would willingly exchange their liberty for apparent security.

INVALIDITY AND OLD AGE INSURANCE

The first invalidity and old age insurance measures were passed in Germany in 1889; by 1916, all occupational categories included under the health insurance program were covered. Employer and employee contributed equal sums, with the government adding an amount equal to approximately one half of the cost of benefits. The scheme was administered by the government with no participation by the insured. When the inflation following the first world war wiped out its reserves, the financial basis of the system collapsed and made necessary an emergency reduction of pensions. Since that time, the increasing age of the population has prevented the accumulation of new reserves out of premiums, and the system has been maintained largely by government subsidy.

Germany's old age pensions were too small to support beneficiaries without supplementary sources of income; the same is true of American pensions, although they are somewhat higher. This fact makes it necessary for the majority of pensioners to apply for relief and defeats the prime purpose of old age insurance.

UNEMPLOYMENT INSURANCE

Unemployment insurance was instituted in Germany in 1927, covering all manual, domestic and agricultural workers in low income groups. Administration was by an autonomous body with local, district and national offices. Rates were set at 3½ per cent, with employers and employees contributing equally. Soon after the plan went into effect, the depression caused a sharp curtailment of benefits; thereafter the program was supported by government subsidy and became a system of relief rather than insurance. Failure of the program can be attributed to the fact that unemployment is not an actuarial risk and unemployment insurance cannot, therefore, have a sound financial basis.

American unemployment insurance has not as yet faced the test of an economic decline. However, it stands to reason that a substantial increase in unemployment will quickly eat up the reserves of the system and an extended depression will throw beneficiaries on the relief roles when the insured period has expired.

1. Sulzbach, W.: German Experience with Social Insurance. Studies in: Individual and Collective Security, no. 2, National Industrial Conference Board, New York, 1947, 134 pp. Price \$1.

CONCLUSION

Two trends are apparent in the history of German social insurance: general expansion of expenditures, benefits and coverage; and increasing use of government subsidy to supplement employer and employee contributions. In 1885, 4.7 million Germans were insured; expenditure for social insurance amounted to 52.2 million marks. By 1931, 23.3 million persons were covered and expenditures had risen to 5,571.7 million marks. While private contributions rose 217 per cent from 1913 to 1930, federal contributions went up 746 per cent, totaling 475.7 million marks in the latter year. In 1929, health insurance took care of an average of 855,000 sick persons a day; 2 million persons were receiving old age and invalidity benefits, and 1,275,000 received unemployment benefits. One German in six—11,189,000 persons—drew part or all of his income from social insurance.

The reasons for this expansion of German social insurance lie more in its value to politicians and bureaucrats than in its accomplishments. Costs of administration were high. The programs restricted the freedom of the worker to spend his money as he pleased. Assessments on the employer were actually shifted to the worker, who was no better off than under private insurance. During and after the depression, when the programs had degenerated into elaborate relief schemes, the insurance myth was maintained. Unfortunately, once the programs had been put into operation, a bureaucracy was built up which had a strong economic interest in the growth of the system. Moreover, the plans were politically popular. Had German social insurance remained on its original modest scale, it would have avoided many of the difficulties which led ultimately to its collapse.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Act: Applicability to Student Nurse.—The plaintiff filed a petition for compensation under the Workmen's Compensation Act for an injury alleged to have been sustained during the course of her employment by the defendant hospital. From a determination of the Workmen's Compensation Bureau's dismissing the petition for lack of jurisdiction, the plaintiff appealed to the Court of Common Pleas of New Jersey, Hudson County.

On Feb. 6, 1939, the petitioner was accepted by the defendant as a candidate to become a nurse. Prior to this acceptance, she had passed an entrance examination and had paid the established fee. For five months she served as a probationer. Thereafter she was formally accepted by the defendant as a student nurse for a period of training which was to last three years, during which time she was to receive no wage or compensation except room, board and incidentals. At the completion of the training course she was to receive a certificate from the hospital and be eligible to take the examination for registered nurses conducted by the state board. The petitioner's duties were as follows: compulsory attendance at chapel at 6:30 a. m., then breakfast and "at 7 o'clock we are given the night report of the night nurses, we are assigned to patients, take temperatures, give bed pans, make beds, give all treatments, such as enemas, give hypodermics, intramuscular injections and medicines." She worked six days or nights a week, was entirely subject to the control and supervision of the head nurse and in return therefore received room and board plus certain items of clothing and various nursing and dietetics books.

The petitioner alleged that she sustained an injury on March 29, 1940, by accident arising out of and in the course of her employment. The defendant, however, denied that the relationship of employer-employee existed between the parties.

It is fundamental, said the court, that as a necessary prerequisite for recovery under the Workmen's Compensation Act, there must exist the relationship of employer-employee.

After a careful consideration of the record in this case, continued the court, it is my opinion that the status of a student nurse who renders service to the public and to the defendant hospital for the pecuniary gain of the latter is similar to the old time apprentice. The apprentice renders services to his master in some trade or employment with the primary purpose of learning the trade, business or profession of the master. The apprentice usually receives no remuneration for his services outside of his board and lodging. For services rendered by him, no doubt the master received payment from the public. I am not unmindful of the fact, the court continued, that one of the purposes of the defendant hospital in permitting a student nurse to practice her art on the public is to increase her efficiency. Another material purpose is to derive pecuniary gain for the services performed. The plaintiff entered into an agreement with the hospital whereby she rendered services to the hospital and its patients. Can anyone doubt the value and importance of such services? Indeed, it is to be seriously doubted that a general hospital could function without the services of student nurses. In return, she received instruction, training, food and lodging and incidental equipment. This constituted her compensation, and she earned it. Accordingly the court held that the employer-employee relationship did exist between the hospital and the student nurse.—*Heget v. Christ Hospital*, 58 A. (2d) 615 (New Jersey, 1948).

Governmental Hospitals: Right of State Hospital Board to Discharge Employees.—The plaintiffs sued for damages for their alleged wrongful and malicious discharge from employment at the state hospital and from a judgment for the defendants appealed to the Supreme Court of Arizona.

The plaintiffs contended that they were wrongfully discharged from their employment by the state hospital board, without just cause or reason, and that such action was taken by the board contriving wickedly, maliciously and wrongfully to injure them in destroying their good name, credit and reputation. The defendants argued that the state hospital board was strictly within its jurisdiction and acting in a quasijudicial capacity in reviewing and determining the cause of the dismissal of the plaintiffs by the superintendent of the hospital and that therefore the board was clothed with immunity from civil liability for any action taken by it in its official capacity, regardless of any allegation of ulterior motive.

It is a general rule of universal application, said the Supreme Court, dating back to the earliest days of the common law, that judges of courts of general jurisdiction are not liable to civil actions for their judicial acts; i. e., the privilege of a judge while engaged in the performance of his judicial function is absolute. This rule of judicial immunity is not continued, but in its protection to judges proper, the court continued, but extends also to any other official who performs a judicial function while acting in a quasijudicial capacity. The statutes of Arizona authorize the superintendent of the state hospital board to discharge an employee for cause. An employee so discharged may on request have the cause of his discharge reviewed and determined by the state hospital board. Continuing, the Supreme Court said that for aught that appears in the plaintiffs' complaint the state hospital board was strictly following the procedure prescribed by statute when the action herein complained of was taken which resulted in separating the plaintiffs from the state payroll. Since it was thus acting strictly within its jurisdiction, it was clothed with immunity from civil liability unless the allegation that its action was taken maliciously makes a difference. There is a division of authority in applying the rule of immunity from civil liability, said the Supreme Court, where it is charged that the act of the quasijudicial officer is done maliciously or corruptly, but the majority rule is that where the quasijudicial officer is acting within his jurisdiction he is not civilly liable, even though he acts corruptly or maliciously. His motives are immaterial. The Supreme Court held that the state of Arizona was committed to this majority rule; the judgment of the trial court dismissing the plaintiffs' complaint was therefore affirmed.—*Wilson v. Hirst*, 193 P. (2d) 461 (Ariz., 1948).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Microscopic Grading of Cancer.—Edmundson points out that the grading of cancer is based on the fact that among growths there is individuality depending on the type of tissue from which the neoplasm has sprung, the site of growth, the type of its growth and the degree of differentiation and dedifferentiation (anaplasia) of the cells of the tumor. Broders graded malignant tissue as 1 if more than 75 per cent of the cells are differentiated, as 2 if 50 per cent to 75 per cent are differentiated, as 3 if 25 per cent to 50 per cent are differentiated and as 4 if zero to 25 per cent are differentiated (or if 75 per cent to 100 per cent are dedifferentiated; i. e., anaplastic). The putting into practice of this criterion literally, necessitating the actual counting of cells, is impracticable, but the associated cytologic changes and morphologic characteristics of the tissue are more easily seen. Since these are direct results of the cellular activity, they furnish accurate evidences of malignant potentialities. The personal factor plays a large part in this system of grading, and objections have been made on the basis of the danger of personal error. The author evaluates other objections that have been made to the system of grading suggested by Broders and to other systems. He believes that Broder's method is the best basis for classification of malignant tumors. The nomenclature pertaining to squamous cell carcinoma and adenocarcinoma in particular is far from standardized. Many surgeons believe that it is an adequate basis on which to prognosticate or to aid in judging treatment. MacCarty has listed nine hundred and fifty terms applied to neoplastic disease and has suggested a system that would seem to be an improvement over the present lack of system. A summary of MacCarty's proposed system of nomenclature is given.

Epidermal Absorption of Drugs.—Luduena and his associates made experiments designed to test percutaneous absorption of selected drugs on the clipped skin of rabbits, using as a leading vehicle 2-(2-ethoxyethoxy)-ethanol ("carbitol"), which is absorbable and can act as a carrier without damage to the skin, another vehicle being octyl alcohol. Epidermal absorption was demonstrated for the following drugs, according to their

typical systemic effects: epinephrine, penicillin and choline esters dissolved in "carbitol" or a mixture of "carbitol" and octyl alcohol. Octyl alcohol mixed with propylene glycol or ethyl alcohol was also effective for promoting the absorption of epinephrine. With the same vehicles, insulin and dihydro-beta-erythroidine were not absorbed epidermally, thus refuting a previous claim made of positive results for insulin. With similar vehicles, large doses of penicillin were not absorbed from human skin. A mixture containing "aerosol OT" (dioctyl sodium sulfosuccinate) damaged the skin. For percutaneous absorption vehicles should be relatively noninjurious, but even under most favorable conditions the dosage of drugs tends to be large and absorption irregular for systemic effects. For superficial (intra-dermal) penetration some of the successful vehicles reported in this paper might be useful for certain drugs, when such action is desired.

Irreversible Toxic "Inclusion Body" Anemia.—Fertman and Doan direct attention to a form of anemia that is characterized by peculiar "inclusion bodies" in the circulating red blood cells. They were first reported by Heinz in 1890. They are readily distinguished from Howell-Jolly bodies, siderocytosis and classic reticulocytosis by their characteristic appearance, distribution and staining reactions. They have gone undetected in most routine clinical laboratories probably because they are difficult to demonstrate in the usual Wright-Giemsa stained and mounted blood films. The attention of the authors has been focused on this phenomenon by the discovery in the blood of an elderly physician with an unexplained refractory anemia, which terminated fatally. After the discovery of "inclusion bodies" in the patient's erythrocytes, it was determined that erythrol tetranitrate was the only drug which had been taken for many months prior to and coincident with the development of the anemia, and to which the patient may have acquired an idiosyncrasy. Since this peculiar anemia persisted and continued to progress even several weeks after the presumed toxic agent was discontinued, some permanent irreversible damage must have been suffered by the erythropoietic tissues. Experimental procedures were undertaken. "Bodies" with similar staining characteristics were reproduced in cats with large oral doses of erythrol tetranitrate and other nitrates. These were generally accompanied by a temporary fall in the red cell count, followed by recovery on withdrawal of the drug.

Anemia in Acute Glomerulonephritis.—Emerson calls attention to the frequent occurrence of anemia in Bright's disease and uremia and presents the case of a soldier, aged 27, who was hospitalized early in an initial attack of acute glomerulonephritis with manifestations of arterial hypertension, hematuria, albuminuria and nitrogen retention, and who was under continuous

observation for fifty days. Studies during this period were concerned primarily with the mechanisms responsible for rapidly developing anemia. Hematologic data were obtained before and after massive transfusion therapy. The administration of group O whole blood containing incompatible anti-A isoagglutinins in the first series of transfusions failed to improve the anemia but initiated a sustained reticulocyte response. Following this therapy there was evidence of increased blood destruction involving both the recipient's and the normal donor erythrocytes. Data obtained following a second series of transfusions employing plasma-free group O red cells, administered during a recovery phase when renal function had improved, indicated that blood destruction had largely abated and that hemopoietic activity was normal. Two factors of undetermined origin are believed to have been implicated in the pathogenesis of anemia in this case: one, the occurrence of abnormally rapid blood destruction, and the other, impairment of blood formation. Both phenomena were associated with the presence of nitrogen retention, despite which, however, a prompt erythropoietic response followed the transfusion of whole blood with quantitative replacement of patient's red cells with donor erythrocytes, suggesting that previous bone marrow inactivity was not attributable to "toxic suppression."

Thoracolumbar Sympathectomy for Essential Hypertension.—Hinton subjected 455 patients, 183 men and 272 women, with essential hypertension to the two stage thoracolumbar sympathectomy during the period from February 1942 to November 1947. Most of these patients were in the advanced stage of hypertensive disease. The total deaths in and out of the hospital were 74, or a total mortality of 16 per cent. The causes of deaths occurring in the hospital were in the order as follows: cerebral, cardiac and renal, while in the deaths outside the hospital the order was as follows: cardiac, cerebral and renal. One should clearly differentiate, in evaluating the end results, whether there has been surgical intervention in the early or in the advanced stages of hypertensive disease. Of 164 patients followed for one year, 93 had a postoperative diastolic pressure of 110 or lower and 71 a postoperative diastolic pressure of above 110. A somewhat more dramatic response is demonstrated by the impressive number of patients whose postoperative diastolic blood pressure falls sharply after exercise, even when their resting pressure has been at higher levels. Such a drop in pressure may well be the result of peripheral dilatation in the muscle bed, unopposed, as, in the intact organism, by splanchnic constriction, thus averting the customary summated response of blood pressure elevation, as in the routine preoperative response to exercise. That relatively advanced age is not necessarily a contraindication to thoracolumbar sympathectomy was demonstrated by the operative results in a group of 72 patients between the ages of 50 and 59 years. The hospital death rate was lower than that of the group as a whole and the two year follow-up revealed that a large percentage of the patients continued to maintain a satisfactory diastolic level. The author feels that thoracolumbar sympathectomy has a definite place in the treatment of hypertensive vascular disease, but its role in cases of advanced disease is chiefly that of palliation.

Diagnosis of Tuberculosis in Presence of Silicosis.—Lee investigated 100 patients with silicosis for the presence of tuberculosis. A complicating active tuberculous condition must be suspected if cough is becoming increasingly productive or if hemoptysis, pain or loss of weight is present. Limited chest expansion on one side, rales and elevated temperature are suspicious signs. Radiologic changes suggestive of a tuberculous process include coalescing shadows, especially if unilateral or increasing in extent, large hilus glands, cavitation or displaced trachea. The absence of a cutaneous reaction to a 10 mg. dose of old tuberculin probably rules out tuberculosis unless the patient is acutely ill. The only definite proof of the existence of a complicating tuberculosis in silicosis is the demonstration of tubercle bacilli.

Prefrontal Lobotomy.—Oltman and her associates say that 107 patients have undergone prefrontal lobotomy at the Fairfield State Hospital in Connecticut since May 1946. Most of these patients had chronic mental illness with an extremely unfavorable prognosis. The results of lobotomy were encouraging in that 86 of the patients showed some improvement, 15 remained unimproved, 5 died and the results in 1 could not be evaluated because of physical complication. Thirty per cent of the patients were sufficiently improved so that they would leave the hospital on an indefinite visit. Convulsive seizures represented the most frequent complication, occurring in approximately 10 per cent of the group. Hostile, aggressive, chronically disturbed patients appear to derive the greatest benefit from this operative procedure.

Synthetic Resin for Antacid Ulcer Therapy.—Kraemer says that in 1938, while seeking an improved antacid, he discussed acid adsorbents with a water purification engineer who had investigated the iron exchange properties of certain synthetic plastic resins. The antacid synthetic resin with which the author is concerned in this report is a phenol formaldehyde condensation product, which is known as "amberlite IR IV" in the chemical trade and which has been given the pharmaceutical trade name "resinat." When this resin was compared with calcium carbonate and with aluminum hydroxide, it was found that its neutralizing power was less than that of calcium carbonate but better than of the aluminum hydroxide suspension. The author discusses the usefulness of this resin in treating peptic ulcer, presenting diets and medication schedules. So far 100 persons with gastric ulcer have been treated with this resin. Eighteen of these patients were hospitalized because they required blood transfusions on account of severe hemorrhage or required surgical treatment. The bleeding patients did rather well with the resin treatment. Of the 82 ambulant patients 76 have been free of symptoms. In all, 85 per cent of the patients have been kept symptom free on the ulcer regimen using resin as the only antacid. None of the patients have had side effects as a result of resin therapy. Particularly noticeable is the lack of complaints regarding constipation and diarrhea and freedom from bloating and gas.

Surgical Procedure for Lymphedema of the Extremities.—Macey points out that many cases of lymphedema progress to the point of disability as a result of the development of recurrent cellulitis and lymphangitis, or the enlargement of the extremity to elephantine proportions, or a combination of both. He reviews the history of operative procedures for the treatment of disabling lymphedema and describes the one first

reported from the Mayo Clinic in 1940. The extremity should be elevated before the operation for two days and drained of most of the lymphedematous fluid. If cellulitis is present, penicillin should be used two to three days preoperatively and continued postoperatively until the second procedure of the operation is completed. Diagrams accompanying the description of the surgical technic show (1) the cutaneous incision of the leg and (2) the subcutaneous dissection of the diseased tissue and the application of split skin grafts over the muscle sheaths and peritendinous structures. Of the 7 patients whose cases are reviewed 5 have had excision of all of the lymphedematous tissue below the knee, and 1 patient has had only the first stage procedure on the medial aspect of the leg. One patient had lymphedema of the upper extremity and has had complete excision of the diseased tissue below the elbow, combined with skin grafting. In this instance of excision and skin grafting of the upper extremity, the result was excellent. Of the 6 patients in whom the lower extremity has been treated, 4 have had excellent results. In 1 of the 2 remaining patients, superficial ulceration in the graft developed, but the patient has been active and the postoperative decrease in the size of the extremity has been maintained. In the remaining case a long follow-up was not obtainable but at the end of one year the skin grafts were in good condition and the elephantine proportions of the extremity had been relieved. The author feels that recurrent cellulitis associated with chronic lymphedema is best treated by excision of the disease-bearing area and by skin grafting.

Primary Closure of Compound Fracture Wounds.

This report by Davis is based on 150 consecutive cases of compound fracture. Twenty-eight patients were treated during the years when neither sulfonamide drugs nor penicillin were available. In the next four years 83 patients were treated with sulfonamide drugs. In the last two years 39 patients were treated parenterally with penicillin, and in addition a sulfonamide compound was dusted into the wound. During the last five years a blood bank has facilitated the generous use of transfusions, and a diet high in protein has been prescribed. It is sometimes impossible and frequently inadvisable to do combined immediate treatment of shock, debridement, internal fixation and closure. For this reason different approaches, depending on the immediate requirements of the individual patients, are outlined in 7 case reports. One hundred and thirty-one, or 87 per cent, of the wounds healed by first intention. About midway in the series it became apparent that the most frequent cause of failure of healing by first intention was the attempt to preserve questionable skin. It is now realized that questionable skin edges jeopardize the result long after the deep tissues have healed. When adequacy of the circulation in a skin flap is doubtful, the tourniquet is removed; if vitality of the flap is not demonstrated, the flap is resected. When longitudinal flaps can be mobilized and drawn together to cover the denuded area, this is done in preference to placing a split graft over the defect. Frequently it is possible to bring the wound edges together without tension by undermining them and using relaxation sutures of stainless steel wire. The results of the described treatment have been superior to those obtained by previous methods. Improved results are attributed, first, to the compression dressing; second, to immediate coverage of the surface defect with skin or a split skin graft, and, third, to immediate or delayed internal hairline reduction, with metallic fixation. The hazard of primary suture is greatly reduced by penicillin and whole blood.

Response of Bacterial Populations to Penicillin.—

Experiments reported by Spicer and Blitz show that penicillin is capable of destroying susceptible bacteria by lysis or otherwise under normal cultural conditions in amounts possible to maintain in the body of the patient. The destructive action of penicillin on sensitive bacterial strains is not complete. A residuum of viable organisms always remains, which is capable of withstanding the destructive action of the antibiotic but is inhibited from multiplying in its presence. Large and small amounts of the drug have the same inhibitory effect on these remaining organisms. The findings suggest that bacterial cultures do not constitute a homogeneous population but that individual members may possess different characteristics as to the manner of reaction under the influence of the antibiotic. Success of penicillin therapy depends directly on the number of residual organisms left viable after the initial treatment. The small numbers of residual viable organisms in strains of *Pneumococcus*, *hemolytic Streptococcus*, and some strains of *Staphylococcus*, as shown by tests, may account for the dramatic results so often obtained with penicillin when used in the treatment of acute infections caused by these organisms. On the other hand, the large numbers of viable organisms found of the *Streptococcus viridans* strain may account for the protracted treatment with penicillin necessary in cases of subacute bacterial endocarditis in which *Str. viridans* is the most frequent etiologic agent.

Structural and Functional Alterations of Liver.—The histologic picture of the liver as seen in biopsy specimens obtained by aspiration or laparotomy from 130 patients with various types of hepatic disease, was compared by Franklin and his co-workers with tests of hepatic function performed at the time of biopsy. Thirty-five of these patients were repeatedly studied. The incidence of diffuse damage to hepatic cells, focal necrosis, regeneration, distorted reconstruction, periportal activity, fatty metamorphosis, and mobilization of Kupffer cells was compared statistically with the results of each of different hepatic function tests. A significant correlation was found between diffuse damage to hepatic cells and albumin/globulin ratio, cephalin-cholesterol flocculation, thymol turbidity, and retention of sulfobromophthalein sodium; a lesser degree with highly elevated serum bilirubin, reduced plasma vitamin A, increased prothrombin time, and slightly elevated alkaline phosphatase. Correlations were not elicited between parenchymal damage and total serum protein, total cholesterol, cholesterol-ester ratio, urinary urobilinogen, stool urobilinogen, alkaline phosphatase in general (and markedly elevated alkaline phosphatase specifically), nonprotein nitrogen or sedimentation rate. Focal necrosis, in contrast to diffuse damage to hepatic cells, was not associated with significant changes in hepatic function. The same was found with fatty metamorphosis. Regeneration showed a correlation with increased thymol turbidity. Distorted reconstruction of the lobular pattern (as seen in cirrhosis) was related to cephalin-cholesterol flocculation, thymol turbidity and elevation of sedimentation rate. Kupffer cell activity appeared related to elevated serum bilirubin and pathologic albumin/globulin ratio.

Resection of Coarctation of Aorta.—Bradshaw and his co-workers performed resection of aortic coarctation with subclavian aortic anastomosis on a boy aged 16. There was no suggestion after operation of any paralysis in the legs or left arm. Death from pulmonary edema and atelectasis ensued twenty-six hours after intervention. Necropsy revealed that the anastomotic side was partly obstructed by a thrombus. Long intestinal clamps were used to occlude the vessel ends while this anastomosis was being completed, and it was difficult to keep the cut ends of the vessels immobile in accurate end to end approximation. The fine sutures being used broke with annoying frequency. An attempt was made to design a clamp which would firmly grasp the aortic wall between parallel bars without crushing, and which would permit the vessel ends to be accurately approximated to each other and immobilized. Such a clamp was made by the Department of Physiology, Jefferson Medical College, Pa.; the instrument consists of two clamps having parallel jaws, the pressure on the jaws being accurately adjustable by means of a knurled nut; an octagonal rod can be inserted into square holes in each clamp so that it holds them in constant alignment with each other and permits them to be moved to or from each other. A handle can be attached to either end of the bar; this handle can be moved through a wide range with respect to the bar and locked in any position desired. When in use the clamps can be removed from the bar or left on it and placed transversely across the aorta one above and one below the segment to be resected. The jaws can be closed to any desired pressure by turning the knurled nut and the aorta can thus be occluded. By placing the aorta in each clamp equidistant from the tips of the clamp, the aortic ends will be brought in accurate end to end position when the clamps are joined by the bar and approximated. This instrument was used experimentally on 15 dogs. The aorta was approached in each animal through the left side of the chest, and segments of aorta varying in length from 4 to 12 mm. were excised.

Aortic-Pulmonary Anastomosis for Pulmonary Stenosis.

—Potts performed aortic-pulmonary anastomosis on 29 children between the ages of 4 months and 12 years, 26 of whom had pulmonary stenosis (tetralogy of Fallot) and 3 had tricuspid atresia. There have been 4 deaths, or a mortality of 13.8 per

cent. Twenty-four of the 25 who survived the operation were definitely improved; cyanosis was largely relieved and the patients are living fairly normal lives. One survivor, a 4 month old child, was improved, but cyanosis was still present during crying. Postoperative complications have not been troublesome. In performing the anastomosis a clamp was used which encircles the aorta and pinches off a small lip of it to which a pulmonary artery can be anastomosed. At the same time the clamp allows plenty of blood to continue to flow through the partially constricted aorta. This technic, worked out in the experimental laboratories of Northwestern University Medical School, was slightly modified: The pulmonary artery is not tied to the anterior lip of the clamp only; instead, one end of the ligature is carried through the posterior lip of the clamp first and then through the anterior. The other end of the ligature is threaded through the same lips in the opposite direction. This brings the pulmonary artery to the aorta in better position for anastomosis. Microscopic study of sections cut from the walls of the anastomotic channels produced in dogs indicates that it is unnecessary in aortic-pulmonary anastomosis to appose the vessels intima to intima. Although intima to intima suture in general is preferable, the author does not believe that it makes any difference in this operation in which the differential in pressures is so great. While the most suitable age for operation is probably between 3 and 7 years, successful anastomoses were performed on 2 children below 1 year of age.

Decapsulation of Kidney for Anuria.—Shapiro describes 2 cases in which anuria occurred after the administration of the sulfathiazole and in which the probable mechanism was the toxic action of the drug on the renal tubules. Bilateral decapsulation was carried out in both patients with prompt cessation of the anuria and ultimate complete recovery. Early decapsulation in similar cases is urged because of the danger that irreversible renal changes may occur if the anuria persists too long.

Cancer Cells in Urine.—Schmidlapp and Marshall review observations on 333 cases in which the urine sediment was studied by the Papanicolaou method for the detection of exfoliated cancer cells. The group comprised not only patients with genitourinary neoplasms, but also many patients with non-neoplastic urologic diseases. The results have been better than expected. Falsely positive reports have been few. A suspicious smear report from the laboratory means cancer nearly half

the time, and therefore dictates more study by the usual urologic means as well as by this method. A negative laboratory report decreases the possibility that cancer of the urinary tract is present but does not reliably rule it out. The method as now applied is of little value in the detection of benign tumors and is of greatest value for cancer of the bladder (but not benign papilloma). It is advisable to examine more than one specimen. The authors caution against clinical utilization of the results of one who is just beginning to use this method until a fairly large series has been tested against the usual data, especially biopsy. It is not intended that this method should supplant or exclude recognized methods but rather that it may provide another tool for the detection and study of urinary cancer.

Persistent Cloaca in the Female.—Towsley reports the histories of 2 girls, aged 9 and 7 respectively, who underwent an operation for persistent cloaca. The rarity of this condition is indicated by the fact that a search of the literature revealed only 4 cases. A child thus afflicted is completely ostracized, and the psychologic reaction is so intense that the condition should be corrected before the child reaches school age. The creation of a continent anus was accomplished in both of these cases. Even though a sphincteric muscle cannot be identified, a continent anus may be made by carefully separating the muscle fibers of the perineal floor and fixing the anal wall to the skin of the perineum. The physical condition of these 2 patients showed rapid and great improvement. They gained weight and strength. The "hangdog" expression left them and they assumed the appearance and behavior of normal girls.

Ulceroglandular Tularemia Treated with Streptomycin.—Lesser and Miller report use of streptomycin in treatment of 2 patients with tularemia. The first patient, a man, aged 39, involved no particular problem once the diagnosis had been established. He was given streptomycin in daily doses of 3 Gm. for seven days. The response to this treatment was excellent. Case 2 presented a more complicated problem. Although the

clinical response to streptomycin was definite, the subsequent course of the disease indicates probable inadequacy of dosage initially. It may also indicate decreased effectiveness of treatment when a delay occurs between the initial phase of the disease and the institution of therapy. Evidence for relapse as manifested by serologic and clinical changes may be correlated with the retention of living bacteria within the recovered patient. The inability of streptomycin to effect lasting remission in case 2 was probably due not only to this fact but also to development of resistance by the organism to the antibiotic agent. The initial amount of streptomycin used may be considered inadequate in the light of current knowledge.

 *Primary Staphylococcal Pneumonia. D. P. Boyette.—p. 200.

Clinical Manifestations of Glioblastoma.—Hesser presents the histories of 3 patients with glioblastoma, which demonstrate that unobtrusive but significant clinical features can slip by unnoticed. In the first case the clinical diagnosis was thrombosis of the right posterior cerebral artery associated with congenital aneurysm, with a history of subarachnoid hemorrhage. At necropsy, a large invasive tumor of the glioblastoma group was found deep in the right temporo-occipital lobe. Extensive necrosis, cystic degeneration and hemorrhagic extravasation were evident. In the second case the clinical diagnosis was epidemic encephalitis and possible tumor of the brain, but necropsy revealed a large cystic and necrotic glioblastoma multiforme. The third case resembled the first one in that symptoms of cerebral and subarachnoid hemorrhage were associated with more definite evidence for tumor of the brain. In an effort to analyze the clinical characteristics of these tumors more critically, 50 cases, diagnosed "glioblastoma multiforme" by operative biopsy (40 cases) or at necropsy (10 cases), were reviewed. There were about twice as many men as women. The onset of symptoms was insidious with gradual progression in 25 cases, rapid or apoplectic in 20 and gradual with sudden or episodic aggravation in 5. Stereoscopic roentgenograms of the skull were made preoperatively in 47 patients and demonstrated changes in 13. Electroencephalography was of diagnostic and localizing value in 13 of the 28 cases in which it was done. Pneumoencephalography gave confirmatory diagnostic information preoperatively in every instance in which it was performed. The data presented indicate pitfalls in the differential diagnosis of malignant tumor of the brain from other varieties of intracranial diseases. These include: age and the presence of arteriosclerosis and/or hypertension; ictus suggesting cerebrovascular disease; lack of localizing symptoms or signs; temporary clinical improvement; normal eyegrounds; mental symptoms suggesting toxic, inflammatory or degenerative cerebral disorder, and overemphasis on historic or other data to the exclusion of subsequent clinical developments. Clinical features favoring the diagnosis of glioblastoma multiforme included: short duration of symptoms or episodic aggravation, headache with vomiting, mental disturbance, convulsions or syncope, neurologic signs, changes in cerebrospinal dynamics, abnormal electroencephalogram and roentgen changes. If any doubt in diagnosis exists, it is better to err in the direction of looking for tumor of the brain than to consider sparing the patient the risk of pneumoencephalography. Contraindications to this procedure are few.

Primary Staphylococcal Pneumonia.—Boyette says that between 1936 and 1947 there were 27 cases of primary staphylococcal pneumonia in Watts Hospital, 5 of which were fatal. Complications occurred in 10 of the 27 cases. In the 14 cases treated with penicillin since it was introduced in 1943 there has been only 1 case of empyema and no deaths. Penicillin, intramuscularly, intrapleurally and by inhalation has been the factor responsible for lowering the mortality rate and the

incidence of complications. It is to be assumed that with the liberal use of sulfadiazine and penicillin in modern practice many cases of staphylococcal pneumonia are nipped in the bud and therefore go unrecognized. Staphylococcal pneumonia is not dreaded now as it formerly was, but it still demands respect as a virulent disease which is controlled by vigorous therapy.

Health of Arc Welders in Ship Construction.—This report by Dreesen and his associates presents the clinical and environmental findings of a cooperative investigation into the respiratory health hazards of shipyard arc welders who were working with coated electrodes on bare steel or galvanized steel. Physical examinations were made on 4,650 persons including 2,950 men and 1,700 women employed in seven shipyards. About 1 out of every 4 persons examined was a non-welder, and the medical findings of this group served to control the clinical observations on welders. Some of the conditions noted, which were possibly related to welding exposure, include a respiratory symptom complex (pharyngitis, rhinitis and conjunctivitis), arc welder's siderosis, cardiovascular hypotonia and rather characteristic occupational stigmas of certain arc welders caused by burns of hot slag or molten metal. These conditions were either infrequent or of a low order of severity. Blood studies failed to reveal serious dyscrasias. Gastrointestinal symptoms were infrequent. There was no indication that welding fume predisposed to pulmonary tuberculosis. In general the concentrations of welding fume and gas observed in the environmental phase of the study were relatively low and the clinical findings were minimal.

Boeck's Sarcoid in Children.—According to Reeves and his associates different organs and tissues are involved in sarcoidosis. The disease has been seen most frequently among Negroes. Of the 13 children analyzed in this series, 9 were Negro and 4 white. The ages of the children varied between 9 and 14 years. The authors feel that the disease may have

been overlooked in many younger children. After presenting several case histories, the authors stress that disease in children appears the same and runs the same course as in adults, involving in varying degrees the skin, lymph nodes, eyes, bones, lungs and many other tissues. The lesions in mediastinum and lungs tend to clear without demonstrable fibrosis. The usual distribution of the enlarged lymph nodes and the involvement of the nose and eyes aid in the differential diagnosis. The blood studies are often pathognomonic: eosinophilia, monocytosis, increase in the globulin content with a reversal of the albumin-globulin ratio. The disease may be confused with tuberculosis, Hodgkin's disease, sarcoma, leukemia, or the fungous infections. The correct diagnosis is usually reached by skin or lymph node biopsy.

Penicillin for Prophylaxis Against Ophthalmia Neonatorum.—Franklin says that for a five month period penicillin in drops was used for prophylaxis in the eyes of each newborn infant delivered at the John Gaston Hospital, Memphis, Tenn. The mothers of the infants studied were nearly all charity patients, of whom 85.3 per cent belonged to the Negro race. Penicillin was used in the form of the crystalline sodium salt of penicillin. A concentration of 2,500 units per cubic centimeter of sterile isotonic sodium chloride solution was used. A single instillation was given. A total of 1,177 infants was studied in the nursery and in the home during the first two weeks of life. One and one-tenth per cent of the infants exhibited pus in the eyes while in the nursery. This percentage is approximately one half of that observed when a multiple instillation method was used under less favorable conditions and is approximately one sixth the incidence observed in a previously reported series following silver nitrate prophylaxis.

Effect of Caronamide on Penicillin Therapy.—The crystalline compound caronamide, which is 4'-carboxyphenylmethanesulfonamide, is used to check the rapid excretion of penicillin by the kidneys. Sweet and his associates in their studies on the use of caronamide made an effort to establish optimum penicillin-caronamide dosage schedules. They describe observations on reduced penicillin dosage with increased time intervals. Studies were also made to determine whether caronamide would add to the effectiveness of oral penicillin. The toxicity of penicillin was investigated. The authors have given caronamide to 59 patients for an average period of six to seven days, the longest being eighteen days and the shortest two. In 6 instances nausea occurred, but only in 1 instance was it necessary to stop the drug because of the severity of the nausea. In 1 instance a generalized erythematous rash developed, which was caused by penicillin rather than caronamide. Caronamide appears to decrease the renal loss of penicillin, making it possible to increase the time interval between penicillin injections to at least four hours and to decrease the daily amount of penicillin needed by at least one half. Caronamide has shown no evidence of hepatic injury, and only occasionally produces nausea and vomiting. The authors feel that the drug should be withheld in frank renal deficiency. Penicillin ingested orally has been demonstrated to bring about effective therapeutic level when given with caronamide.

Familial Sciatica Due to Herniated Disks.—Meredith describes a family in which the father and 5 of his 6 children had or have sciatica. Six operations for removal of protruded disks at the fourth or fifth lumbar interspaces or both have been necessary to date in this sciatica-afflicted family. None of the 6 patients had a history of a traumatic episode. All were in the fourth or fifth decade of life when operated on. Degenerative

changes seem to predispose to herniation of the nucleus pulposus and such changes may have been the most important etiologic factor of disk protrusion in this family. It is possible that a congenital defect is present in some cases of lumbar protruded disk, especially in those patients in whom there has been no definite traumatic history, as in all 6 of the familial cases herein described.

Propylthiouracil in Preoperative Treatment of Hyperthyroidism.—Clinical experience with propylthiouracil in the preoperative treatment of 300 patients with moderate to severe hyperthyroidism indicates that it is uniformly effective in reducing the basal metabolic rate when given in the daily dose of 200 mg. for primary hyperthyroidism and 300 mg. for adenomatous goiter with hyperthyroidism. Significant toxic manifestations were observed in 6 of the 300 patients treated. In one case a fever reaction occurred. Five patients had depressive changes in the white blood cells; in one this change was typical agranulocytosis. The occurrence of these reactions indicates that propylthiouracil is not a completely harmless drug and that patients receiving it require careful observation. Lugol's solution (strong iodine solution U. S. P.) is now combined with propylthiouracil in all patients with primary hyperthyroidism. The quick action of Lugol's solution produces a more prompt subjective improvement but tends to cause slight delay in the return of the basal metabolic rate to normal. Patients with primary hyperthyroidism respond with an approximate daily drop of 1 per cent in the basal metabolic rate. No death occurred after thyroidectomy in the 300 patients treated with propylthiouracil.

Spinal Anesthesia in Vaginal Deliveries.—The cases reviewed by Rogers include all patients delivered vaginally from September 1943, when spinal anesthesia was first used for deliveries, to July 1947. The total number of vaginal deliveries occurring in this forty-six month period were 5,837, in 5,067 of which spinal anesthesia was used and in 770 nitrous oxide. From 3 to 10 mg. of tetracaine hydrochloride in 1.5 to 2 per cent dextrose solution is used. This solution makes it relatively easy to control the height of the anesthetic. The average dose used is 6 mg. tetracaine, which will ordinarily produce complete anesthesia for one to two hours. The anesthetic is administered with the patient lying on her left side, the head of the table being elevated 2 or 3 inches (5.1 to 7.6 cm.). There were no maternal or fetal deaths and no neurologic complications. Spinal anesthesia is not an obstetric panacea, but when judiciously used affords a safe means of painless delivery.

Permanent Quadrantanopia After Migraine.—Rich says that, although it is well known that migraine often is accompanied with visual hallucinations, it is not generally known that it may lead to permanent visual damage. He describes a woman in whom permanent homonymous quadrantanopia developed after twenty years of repeated attacks of idiopathic migraine. According to Peter, perimetry locates ophthalmic migraine in the visual cortex. It is probably due to spasms in the small vessels of the cuneus. Repeated attacks of spasm in the small vessels may result in permanent occlusion of the vessel with softening of the brain tissue, the functional process then becoming organic. A review of the literature revealed only 13 other cases of this type.

Phlebothrombosis and Pulmonary Embolism.—Diagnosis of phlebothrombosis must be considered when the temperature chart shows unexplained repeated slight elevations. The condition is more prone in persons past the meridian of life, and the highest incidence is between the ages of 50 and 60. If the patient has undergone an operation about a week previous to development of the condition, more particularly if there was herniotomy, hysterectomy, resection of the rectum, prostatectomy, cholecystectomy or operation for perforative appendicitis, and if the patient has been nursed with a pillow placed beneath the knees, the clinician's thoughts should turn to the veins of the lower extremities. The whole lower extremities should be inspected in suspected early cases for swelling, fullness of veins and cyanotic tinge. Finger tip pressure should be applied over each saphenous opening, and, with a stroking motion, the finger is run down the course of each femoral vein, seeking a segment of unilateral localized tenderness. Then follow palpation of feet, legs and particularly the popliteal space. Homan's sign should be investigated, and femoral pulses should be compared. If, following a thorough examination, the diagnosis of femoral thrombosis is reasonably assured, removal of clots and interruption of the femoral vein will forestall many pulmonary emboli. In Britain there are few surgeons who have carried out femoral thrombectomy; the operation has received less attention than pulmonary embolectomy. The latter is a heroic measure requiring special facilities, special instruments and special skill. Femoral thrombectomy requires none of these things. Femoral thrombectomy is indicated: (1) when pulmonary embolism has occurred and the patient is yet in a fit condition to withstand operation and (2) when phlebothrombosis decubiti has been diagnosed with some precision. The author describes femoral embolectomy and says that if it should prove fruitless, ligation of the inferior vena cava should be resorted to.

Symptom Production in Sciatica and Low Back Pain.—Falconer and his associates studied two groups of cases. The first group comprised 100 consecutive patients suffering from disabling sciatica or pain in the lower part of the back, who submitted to operation with a presumptive diagnosis of disk protrusion. The second group consisted of 76 patients with severe sciatica or pain in the lower part of the back, who were admitted initially to medical wards, where they were treated conservatively. Routine myelography performed in patients with sciatica or pain in the lower part of the back, admitted to

the hospital because of severity or intractability of symptoms, has indicated that intraspinal lumbar disk protrusions are present in almost all cases, whether the patient recovers from symptoms spontaneously or only after operation. Myelography, when repeated after spontaneous recovery from symptoms has occurred, usually shows that the intraspinal disk prolapse persists apparently unchanged. A number of further clinical observations are reported, which indicate that pain in the lower part of the back is caused by the disk prolapse alone, presumably through implication of the sinuvertebral nerve of Luschka, and that sciatica occurs only when the disk is prolapsed so that it impinges on a nerve root in its extrathecal course at the level of either of the lower two lumbar intervertebral disks. Secondary changes, probably of intraneural edema, appear within the affected nerve root, which contribute to the production of symptoms by pulling the nerve root tight against the prolapsed disk, thereby causing angulating and other strains within it. These strains, in their turn, excite afferent impulses within the nerve, which on reaching the sensorium produce a sensation of pain referable to the peripheral distribution of the affected nerve root. A slight blocking in conductivity through the compressed segment of nerve root accounts for the associated muscular, sensory and reflex disturbances. The spontaneous remission of symptoms, which often occurs in sciatica, can result from a resolution of the neural changes without an associated resolution of the disk prolapse. In treating sciatica and pain in the lower part of the back, conservative measures, with application of the principle of rest to the lumbar aspect of the spine, should always be tried in the first instance; they are often successful. Surgical treatment should be considered only when conservative measures fail and disability is appreciable.

Neuropathologic Aspects of Thrombocytic Acroangiothrombosis.—Adams and his co-workers review the neurologic and neuropathologic observations in 4 cases of thrombocytic acroangiothrombosis. This is a rare disease of unknown causation, which begins acutely, runs a rapidly progressive course and usually causes death in a few days or weeks. The leading clinical features were fever, purpura, anemia, thrombopenia and symptoms of cerebral disorder, such as muscular weakness, hemiplegia, convulsions, confusion, stupor and coma. The most important pathologic changes were a striking increase in cellularity of the walls of arterioles and capillaries and thrombi of platelets. These vascular abnormalities were pronounced in the brain of each of the 4 patients and were sometimes associated with multiple small foci of parenchymal necrosis and petechial hemorrhages. The neurologic data in 14 reported cases are summarized. Clinically the disease must be distinguished from idiopathic thrombopenic purpura, disseminated lupus erythematosus, subacute bacterial endocarditis and rickettsial diseases. This usually is possible by taking into consideration the total clinical picture and the laboratory data. The diagnosis of the disease can probably be established by bone marrow biopsy, in which platelet thrombi and vascular hyperplasia can often be seen. The brain lesions are believed to represent a unique picture, unlike any other neurologic type of reaction to disease.

Desoxycorticosterone in Addison's Disease.—Ravault and his co-workers treated 7 patients, 5 men and 2 women, between the ages of 20 and 41, who had Addison's disease, with desoxycorticosterone acetate in crystalline form in aqueous suspension by intramuscular route. Animal experiments on adrenalectomized dogs showed that the duration of the effect of the drug in aqueous suspension was much longer than that of the drug in oil. In the patients the dose of desoxycorticosterone acetate in 2 cc. of water varied from 50 to 150 mg. Satisfactory results suggest that the new method of administration may occupy a place halfway between injection in oil and implantation of pellets. The new method is indicated in mild cases of Addison's disease in which one injection of 50 mg. was effective for three weeks, while one injection of 100 mg. was effective for five to six weeks. Implantation of pellets may be preferred in grave cases of Addison's disease, but the new method of administration may be used temporarily to avoid hospitalization required for the implantation and to determine the need of the drug and its optimum dose. No untoward reactions occurred in those cases in which the dose of one injection was not larger than 100 mg. Mild edema resulted in 1 patient from a dose of 150 mg., but disappeared within a few days.

Focal Infection. H. C. van Leeuwen.—p. 647.

Serum Hepatitis.—Bruins Slot reports 2 men, aged 55 and 67, respectively, in whom hepatitis developed after repeated injections of plasma. In both of these cases of serum hepatitis, the gastrointestinal disturbances usually developing at the onset were absent. Many observers consider the so-called arspenamine icterus also as a form of serum hepatitis, which is transmitted by the injection needle. The pathologic anatomy of epidemic hepatitis, serum hepatitis and arspenamine icterus is identical.

Polytendinobursitis.—Dorrepaal reports several patients who showed signs of tendinitis in various parts of the body often associated with bursitis. The heart remained normal. This entity of polytendinobursitis must be differentiated from rheumatoid arthritis, rheumatic fever and fibrositis. The etiology of polytendinobursitis has not been clarified, but the case histories suggest that loss in general resistance and focal infection might play a part. Treatment consists in protecting the involved part from exertion, providing good food and perhaps additional vitamins and in treating the anemic state that might exist.

Exudative Pleurisy and Pregnancy. O. Lassen.—p. 215.
Spontaneous Hypoglycemia—Insuloma. L. Thorling.—p. 217.

Relation of Erythema Nodosum to Tuberculosis.—Primary tuberculous infection was certain in 29 per cent of Ustvedt's 200 cases of erythema nodosum; tuberculous etiology was probable in 37 per cent, could almost surely be excluded

in 23 per cent and was improbable in 11 per cent. He concludes that in Norway only about two thirds of the cases of erythema nodosum can be assumed to be connected with primary tuberculous infection. In practice, every case of erythema nodosum should be treated as if due to tuberculosis until other cause is established.

 *Histamine Contents of Blood in Patients with Ulcus. A. W. Surkes.—p. 264.
 *Analgesic Effect of Calcium in Metastasis of Cancer. J. Körbler.—p. 266.

Histamine in Blood of Patients with Ulcus.—Surkes determined the histamine content in the whole blood of 40 patients, 14 women and 26 men between the ages of 23 and 73, who had peptic ulcers demonstrated on roentgenologic examination. Thirty-two of them presented ulceration of the stomach, and 8 of the duodenum. The disease was chronic in all cases. The quantitative estimation of histamine in the blood was carried out by using Code's modification of the Barsoum-Gaddum method. In 28 patients the histamine values were normal; in 8 patients they were increased slightly, and in 4 patients there was a pronounced increase. The histamine contents were normal in 15 of 19 patients in whom the niche had disappeared and there was a mild increase in the remaining 4 patients. In 4 patients on whom gastrectomy was performed for ulcer of the stomach, the histamine in the blood was determined before and immediately after the surgical intervention. These patients presented a tendency to reduced histamine values after the intervention.

Calcium in Metastasis of Cancer.—Körbler treated 7 patients, 5 women between the ages of 44 and 75, who had cancer of the breast with bone metastases in the legs or ribs, 1 woman aged 51 with adenocarcinoma of the scalp and metastases in the legs and 1 man aged 57 who had cancer of the floor of the mouth with metastasis in the lower jaw, by intramuscular administration of a 10 per cent solution of calciumgluconogalactogluconate ("calcium Sandoz"). Ten cubic centimeters of the solution was injected daily on ten and twenty consecutive days. Pain caused by the metastases was relieved in all cases; this analgesic effect was only temporary in some of the patients but permanent in others. It was obtained with the first injection and in some cases after several injections only. Results were best in metastases in the region of the vertebral column after cancer of the breast and particularly during the first phase of such metastases in which pain may be severe in the absence of any roentgenologic manifestations. An additional, eighth, case is reported in a woman aged 45 who had severe pain associated with metastases of pelvic bones after mastectomy for cancer. She was treated with calcium compound for several weeks. The pain was relieved and calcareous deposits were demonstrated on roentgenologic examination. Although these deposits cannot explain the analgesic effect of the calcium, it is suggested that it might be possible to make these deposits radioactive by the action of neutrons and thus to produce a source of gamma rays within the metastasis.

 Electric Shock Therapy Under Curare. L. Massion-Verniory, E. Dumont, R. Nicaise and H. Reinhold.—p. 150.

Male Hormones in Treatment of Carcinoma of Female Breast.—According to Sicard, the influence of the ovarian secretion on the development of carcinoma of the breast has been proved clinically and experimentally. Castration, either by surgery, irradiation or the administration of androgens, must be regarded as antagonistic, particularly to the development of metastases. The author has employed castration in a number of patients with osseous metastases. He found that the efficacy of surgical castration can be considerably increased by the

administration of testosterone. He describes the different dosage schemes that he employed in the administration of androgens either by intramuscular injection or by implantation of pellets. He now usually administers ten injections of 100 mg. of testosterone every three months. The effect of the implantation of pellets can eventually be complemented by intramuscular injections. To be effective, testosterone must be given in large doses, which eventually leads to the development of male characteristics such as change of voice, hair growth and hypertrophy of the clitoris.

 *Syndrome of Amyotrophic Lateral Sclerosis of Traumatic Origin Treated Surgically. C. Jimenez Diaz and Obrador.—p. 120.
 *Menopausal Hyperthyroidism and Estrogens. P. De La Peña Regidor.—p. 123.

Salicylism in Treatment of Acute Rheumatic Endocarditis.—Arjona and his associates demonstrate that by administering relatively large doses of sodium salicylate and benzoate (8 Gm. for adults) for two or three days and by following this with smaller doses of 4 to 6 Gm., effective salicylism levels can be maintained. The administration of small doses from the beginning also permits useful levels to be attained, but when seventy-two hours go by before they are reached the disappearance of symptoms is delayed. Adequate salicylism levels can be maintained also by the rectal administration of these salts. Rectal administration is especially useful in cases in which symptoms of gastric intolerance appear. An enema of 8 Gm. in an adult, administered by the drip method, and later enemas providing 4 to 6 Gm. permit the maintenance of effective levels of the drug.

Surgical Cure of Amyotrophic Lateral Sclerosis of Traumatic Origin.—Jimenez Diaz and Obrador report a man, aged 48, who fifteen years previously had been in a traffic accident. He was unconscious for several hours and later complained of paresis in both arms and cervical pain. These symptoms subsided gradually, but motor disturbances remained. His hands became atrophied. He resumed his occupation at the end of a year, but force and movement in the hands were still impaired. He had a feeling of heaviness and of pain in the neck. His condition remained stationary for a number of years, but during the last year paresis and atrophy increased. Examination revealed increased reflexes of the lower extremities, and myelography disclosed an obstruction in the cervical column. Operation revealed great hypertrophy of the dura. Freeing the medulla by sectioning the ligamentum denticulatum effected prompt improvement in the motor activity of the hands. This proves the importance of the fixation of the medulla to the internal surface of the dura by the dentate ligaments. Patients with syndromes of the anterior motor neuron of the cervico-thoracic enlargement or of amyotrophic lateral sclerosis, who have a history of trauma, should be subjected to myelography so that possible mechanical obstruction may be detected, the surgical removal of which will produce a cure. The case demonstrates greater vulnerability of the motor fibers in the compressive processes. This explains the preponderance of motor and atrophic disturbances.

Menopausal Hyperthyroidism and Estrogens.—De la Peña Regidor reports the case of a woman, aged 33, who had symptoms of hyperthyroidism after successive removal of the right and left uterine adnexa. The conclusion was reached that her hyperthyroidism was the result of the cessation of the ovarian function. Administration of ovarian hormones checked indirectly the production of substances causing excessive function of the thyroid. The institution of this treatment had the desired effect.

Local Treatment of Tuberculous Lesions with Sulfones. N. Rist.—p. 224.

Fluorescent Screen Roentgen Pictures of Patients Reexamined for Clarification.—According to Fischer and Schinz, mass examination by roentgenograms made with the aid of the intensifying screen is to be considered as a gross method which only rarely will be an aid to definite diagnosis. Roentgenograms made with the aid of the intensifying screen of 2,823 (4.6 per cent) of 65,526 persons who were examined by this method during the period from June 1946 to July 1947 showed positive alterations which required reexamination for clarification. Only 2,532 of them were available for such reexamination. Eight hundred and fifty (29.8 per cent) proved normal, while positive clarification results were obtained in the remaining 1,682 persons; 808 (1.23 per cent) had pulmonary tuberculosis, and this was not known previously in 644 (0.99 per cent) of them, while it was known to the family physician in 164 cases (0.24 per cent). There were 37 open cases among the previously unknown cases and 8 open cases among those previously known. Of the 506 inactive, closed cases of pulmonary tuberculosis which were demonstrated on reexamination, 388 (0.59 per cent) had not been known previously and 118 (0.18 per cent) had been known previously. There were in addition 257 active closed cases, 219 of which were not known previously, while 38 were known. Diagnosis of closed active cases is of less importance prophylactically than that of the open cases, but is of the greatest importance to the patient. Control of these patients is essential, since transition from the inactive phase of the disease to the active phase may take place at any time. The same applies to the inactive closed cases.

Local Streptomycin Treatment in Pulmonary Tuberculosis.—Tanner and his co-workers treated 6 men with pulmonary tuberculosis and cavities demonstrated by tomography, with streptomycin. A total dose of 18 to 29 Gm. of the drug was injected through the chest wall directly into the cavity in fractional doses of 0.2 to 0.5 Gm. In 5 an additional 13.5 to 75 Gm. of the drug was administered by intramuscular route, so that the total dose of the drug varied from 42.5 to 97 Gm. The sixth patient had received 115 Gm. of the drug by the intramuscular route previously but without definite results. Treatment of this patient and another patient was a failure because the drug was expectorated and because of the resistance to the drug caused by the previous parenteral treatment with streptomycin. The other 4 patients showed a pronounced reduction in the size of the cavity after a short time. There was also a partial regression of the process in the lung; the amount of sputum and the number of bacilli were reduced. This method of treatment is recommended particularly for cases of pulmonary tuberculosis with cavities in which collapse therapy is not feasible, or in which it was ineffective. Daily introduction of 0.5 Gm. streptomycin in a 1 cc. solution into the cavity combined with 1 Gm. of the drug in two fractional doses per day by intramuscular route may be employed as the sole treatment or as a preparatory treatment for surgery. Untoward reactions may be avoided with careful technic. Not a single accident or dissemination was observed with six hundred local injections.

Semaine des Hôpitaux de Paris**24:633-654 (March 14) 1948. Partial Index**

Sternal Marrow in Evolutive Course of Nephritis. H. Metzger and J. G. Lévy.—p. 640.

*Melanophore as an Aid to Diagnosis of Pregnancy: Its Application and Value. L. Servantie and G. F. Moretti.—p. 642.

Melanophore in Diagnosis of Pregnancy.—Servantie and Moretti modified Hogben's *Xenopus* test for pregnancy by using frogs (*Rana esculenta*) in tests. Hypophysectomy was performed on the frogs under ether anesthesia. Although the discoloration of the animals becomes complete within five to six hours, it is advisable to examine microscopically the interdigital membrane of the posterior paw of the frog to verify whether

all the melanophores are punctiform without asperities or digitations. No animals should be used for pregnancy tests which do not present a complete contraction of the melanophores. The urine of the woman to be tested for pregnancy (one tenth of the weight of the frog) is injected into the dorsal lymph sac of the animal. The reaction was negative in two hundred instances in which the urine of normal men or women was injected into the frogs. The reaction was positive in one hundred instances in which the urine of pregnant women was injected into the frogs. An assay of the melanophore-expanding hormone was made in 36 women in whom the duration of pregnancy varied from one to nine months; the melanophoric index on the average varied from 2.1 in the first month of pregnancy to 1.7 in the ninth month of pregnancy. The index of expansion may be increased from 1.8 or 2 to 2.5 or 3 by bringing the urine in contact with kaolin or aluminum for twenty-four hours before it is injected into the hypophysectomized frog. The frog test is to be considered as a safe and specific test for pregnancy. It proved to be strongly positive in two instances in which the Brouha test was falsely negative.

Primary Cancers of Lung. P. Nicaud.—p. 839.

*First Clinical Observation Concerning Effect of Vagotonine in One Case of Fatty Hepatomegalia of Pancreatic Origin. J. Caroli and J. Etève.—p. 850.

*Temporal Arteritis. L. Justin-Besançon, H. P. Klotz, A. Rubens-Duval and H. Sikorav.—p. 863.

Effect of Vagotonine (Pancreatic Hormone).—Caroli and Etève report a case of fatty liver associated with chronic calcified pancreatitis in a man aged 43. There were general anemia, loss in weight and fatty diarrhea. Daily administration of crude pancreas proved ineffective. Three tablets (75 mg. of the crude or 3 mg. of the pure substance) of vagotonine, the pancreatic hormone isolated by Santenaise, were given daily by mouth; later 300 mg. of crude vagotonine or 9 mg. of pure vagotonine was given. Improvement in the general condition and a pronounced decrease in the enlargement of the liver resulted from continued treatment for six weeks. This observation supports the results obtained by Santenaise with vagotonine in depancreatized dogs. The livers of the sacrificed animals which had been given insulin and vagotonine were normal, while the livers of the animals treated with insulin alone presented a considerable excess of fat. The general condition of the depancreatized dogs treated with insulin and vagotonine was excellent in contrast to the poor condition of those treated with insulin alone. Vagotonine appears to have a lipotropic effect analogous to that of the lipoic substance extracted from the pancreas by Dragstedt.

Temporal Arteritis.—Justin-Besançon and his co-workers report 1 case of temporal arteritis in a woman aged 70. The disease is rare in France. The patient presented a temporal and a general syndrome. There were definite signs of inflammation of the two temporal arteries. They were increased in size and there was swelling and redness of the skin overlying the arteries. There was considerable tenderness on palpation; it revealed hypertrophy of the two temporal trunks, which were hard, pulseless and thrombosed. Some segments of the occipital arteries and of the left facial artery presented an identical picture. All the other branches of the arterial tree appeared normal. The patient suffered severe headaches, particularly in the temporal, occipital and nuchal regions. The patient was pale and her face had an anxious expression because of the intense pain. Temperature varied from 100.4 F. (38 C.) to 101.4 F. (38.5 C.). A left temporal arteriectomy was performed. Microscopic examination revealed a subacute arteritis obliterans, with a focus of fibrinoid necrosis and macrophagic giant cell granuloma. Pain was alleviated considerably. The fever did not subside in spite of the arteriectomy. Penicillin proved ineffective. Sixty-four grams of sulfadiazine was administered within eight days; the temperature was restored to normal; pain and swelling disappeared almost completely, but the absence of pulsation persisted. A follow-up of seven weeks is too short to decide whether a definite recovery or a remission occurred. Temporal arteritis is a clinical, anatomic and pathologic entity. Despite its diffuse character, the term temporal arteritis should be retained to emphasize the major symptom and facilitate the diagnosis.

Book Notices

Clinical Methods of Neuro-Ophthalmologic Examination. By Alfred Kestenbaum, M.D., Assistant Clinical Professor of Ophthalmology, New York University, New York. Fabrikoid. Price, \$6.75. Pp. 384, with 64 illustrations. Grune & Stratton, 381 Fourth Ave., New York 16, 1946.

In his introduction the author states that the book is intended for a review of clinical methods of ophthalmologic examinations helpful in neurologic diagnosis. He makes no attempt to make it a complete textbook of neurology and omits such diseases as heredodegenerative disorders of the retina and cerebromacular degenerations because they do not present ophthalmologic signs or tests used for neurologic diagnosis, though both the eyes and the nervous system are involved. There are ten chapters presenting, in order, anatomy of the optic pathway, fields of vision, pathology of the optic nerve, chiasmal lesions, retrochiasmal lesions of the optic pathway, eye muscle palsies, gaze movement and gaze palsy, nystagmus, disturbance of symmetrical eye movements, pupil accommodation, palpebral fissure and functional disturbances. There are no photographs or plates, only schematic drawings, which are pertinent and clear. The author describes the methods of examination and discusses the results in various pathologic conditions. He presents field charts to illustrate the types of defect in various locations of the lesions and in parallel columns mentions the defect and the probable underlying pathologic condition. He presents a method of recording the site of retinal lesions which is useful. There are several differential diagnoses presented in parallel columns for quick review. Several of his own tests and innovations are presented, as for example the capillary number test, i. e., counting the number of very small blood vessels on the edge of the disk in optic atrophy. He claims that normally about ten are visible. In optic atrophy they are reduced below six—even as few as three. The book is based on lectures to neurologists and ophthalmologists and is presented in lecture form. It is a most practical presentation of the subject and is well worth careful study by all students of ophthalmology and practitioners.

Man—Weather—Sun. By William F. Petersen, M.D. Fabrikoid. Price, \$10. Pp. 462, with 294 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1947.

It is in no sense a pleasure to review this book—a sizeable volume which might wisely have remained unpublished in these days of an already too voluminous medical literature. The format of the book follows the publisher's usual style and quality of physical production; its content, however, evinces such severe faults in technical approach and logical deduction as to exclude it from the field of scientific literature. The relationships of man-weather-sun deserve far more intelligent treatment than they here receive!

Petersen sees "Man as a Cosmic Resonator," responding in numerous physical and chemical ways to the passage of polar and tropical "fronts." He follows three young men—triplets—intensively for forty-two days and finds their ups and downs occurring with or just after the passage of "fronts." Indeed, how could it be otherwise, when he labels thirteen "cold fronts" as passing over Chicago in the forty-two day period of observation? Everything happening in Chicago most of the time must perforce take place with or just after the passage of a "front!" Close inspection of the numerous "biometeorograms"—from which Petersen draws such positive conclusions—fails to reveal any consistent and significant visual relationship; to apply statistical methods as corroboration of relationships not otherwise evident is only to add absurdity to the situation. Statistical methods are useful only in quantitating the significance of relationships observable by other means.

Just a few instances of the illogical reasoning which abounds throughout the book: 1. There were thirteen "cold fronts" and six "warm fronts" listed as passing over Chicago during the forty-two day triplet study—one "cold front" about every three days—and still Petersen naively states (page 30) that the thirteen pulse crests of Harold all "followed periods of cold!" Each of them must also have preceded a period of cold! 2. Graphs are presented (in eight different sections) to show a different pattern of temperature and barometric pressure behavior for the four days before and the four days after

periods of pulse or other crests, overlooking entirely the fact that there can be no such patterns when most such four day periods overlap the passage of at least two cold fronts irregularly spaced. 3. Figure 118, page 135, shows in clear form the sharp monthly or menstrual cycle in basal metabolic rate of a female subject for a nine month period, but Petersen quite dogmatically relates these premenstrual rises and sharp menstrual declines in metabolic rate to coincidental or preceding changes in outdoor temperatures!

But why go on? Indexes of functional activity in the body either rise or fall as environmental temperatures fluctuate with passing "fronts"; hence Petersen sees a causal relationship! A single attack of acute appendicitis rates a whole chapter in the book; day to day passage of weather "fronts" is said to affect the day to day sex ratio of infants being conceived, when the only method of approximating the day of conception was to go back two hundred and eighty days from the time of birth—probably not over 20 per cent of all conceptions would fall within one Chicago weather cycle of this two hundred and eighty day period!

The volume is not scientific, but neither is it good nonscientific literature. Faulty punctuation, loose and top-heavy sentence structure, little regard for proper paragraphing, tiresome repetition, and over-use of italics constitute but a few of its faults. Of all Petersen's writings, it does most clearly (?) present his philosophy regarding "Man as a Cosmic Resonator," but perhaps most tragic and significant is the final word of his closing chapter—set in broken type—Chaos.

Sex Education: A Guide for Parents, Teachers and Youth Leaders. By Cyril Bibby, M.A., M.Sc., F.L.S. Cloth. Price, \$2.50. Pp. 311. Emerson Books, Inc., 251 West 19th St., New York 11, 1946.

This is a British book from a British point of view, but it differs little from American productions on the subject except that it is much more lengthy and contains a great deal of argumentation in favor of what is generally taken for granted in the United States; namely, the necessity for teaching about sex, the desirability of doing so in the home, and the advisability for having the school take over responsibilities which belong to the home but are not accepted or properly discharged in the home. The book is well written and comprehensive and should be a useful reference book and may even be used as a textbook at the college or perhaps twelfth grade level. There is a special preface for the American edition. The work proper consists of an introductory chapter which poses the problems, followed by chapters on the social setting, the parent's part, the school curriculum, sex problems in the school, the nature of adolescents, the search of the adolescent for knowledge, and a chapter on educating the educators. Almost as prominent as the chapters are the appendixes, of which there are six, dealing with a tentative scheme for sex education, suggestions for practical activities, sources of material and advice, specimen circulars, specimen lectures and a guide to further reading. This may be regarded as one of the better productions in the greatly overwritten field of sex education.

Operative Gynecology. By Harry Sturgeon Crossen, M.D., and Robert James Crossen, M.D., Assistant Professor of Clinical Gynecology and Obstetrics, Washington University School of Medicine, St. Louis. Sixth edition. Cloth. Price, \$15. Pp. 999, with 1334 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

In order to avoid increasing the size of the book unduly because of new material, the authors removed considerable historical data. This does not at all detract from the book.

The title of the book is "Operative Gynecology"; yet a considerable part of it is devoted to diagnosis, etiology, histology, pathology and symptomatology. Likewise, numerous illustrations are included which have no bearing on operative technic. In fact, in the first chapter, which deals with "Myoma of the Uterus," ten full pages and a colored plate are devoted to illustrations of different types of uterine myomas.

Throughout the book whole sections of published articles by the authors and others are reprinted in small type. There appears to be too much of this. Likewise, because of the senior author's special interest in foreign bodies left in the abdomen, there are many pages of text and illustrations assigned to this subject.

There is a large and well written section on radiation therapy which is abundantly illustrated. The authors discuss radium and roentgen treatment for both benign and malignant conditions. They believe that radiation in the handling of climacteric patients with troublesome myomas is effective in stopping myoma activity and associated symptoms in 90 per cent of properly selected cases. It reduces to one third the risk of future malignancy, but it still leaves a risk of 0.89 per cent, which definite risk must be given due weight in deciding between radium treatment and operative removal in the individual patient with her special local and general conditions.

Many new illustrations have been added and a few old ones deleted. The three pages of text and the eight illustrations on the old Dudley operation could have been omitted without detracting from the book. In successive editions the authors have wisely decreased the amount of space devoted to retrodisplacements of the uterus. In the 1930 edition, 80 pages and 95 illustrations were given over to retrodisplacements, but in this edition only 35 pages and 67 figures are devoted to this subject.

The high standard of previous editions is maintained in this edition both by the authors and the publishers. The book is well written and abundantly illustrated, and it will undoubtedly continue to retain its well deserved popularity as a textbook on operative gynecology.

Health Instruction Yearbook 1946. Compiled by Oliver E. Byrd, Ed.D., Associate Professor of Hygiene, Stanford University, Stanford University, California. Foreword by C.-E. A. Winslow, Dr.P.H. Cloth. Price, \$3. Pp. 398. Stanford University Press, Stanford University, California; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1946.

This is the third volume in a series of yearbooks of which previous volumes have been reviewed in *THE JOURNAL*. Except for the anomalous dating which has previously been discussed and which puts a 1946 date on material derived largely from 1945, this is a fine job which ought to be continued. The first book was good and the second better. This is better still. In the "1946" edition appears a foreword and preface plus twenty-one chapters dealing with various phases of health, as social accomplishment; social problems; nutrition and health; excretion and health; exercise and body mechanics; fatigue and rest; mental health and disease; heredity and eugenics; infection and immunity; chronic and degenerative disorders; habit forming substances; care of special organs; safety; health and physical environment; health services and facilities; family health, school health, occupational health; community health services; trends and possibilities; international health; a bibliography; an author index, and a subject index.

The items are well selected. For example, in the chapter on infection and immunity one finds first of all a general survey of the situation, which takes two pages. Following this are items dealing in order with venereal disease in Honolulu; recent advances in control of infectious diseases; articles on penicillin; studies on infectious hepatitis; SN7618 as an effective new agent against malaria; failure of sulfonamide drugs to prevent epidemics of streptococcal disease; articles on disinfection of air by germicidal vapors and mists and on ultraviolet control of respiratory infections; vaccination against influenza; immunization against whooping cough; articles on various aspects of tuberculosis in the armed forces and among civilians; studies on streptomycin; plague in the United States; fungi in lung disease; articles on poliomyelitis; complications from scarlet fever; German measles during pregnancy; compensation for typhoid carriers; the increase of diphtheria in Michigan; postage stamps and disease; pigeons and virus pneumonia; smallpox in San Francisco; articles on the venereal diseases, and on public health uses of DDT. The reporting in each instance is brief, factual and noncontroversial.

In the introduction the authors take cognizance of the previous recommendation that the dating of the books be changed. Without wishing to be objectionably insistent, we repeat that the dates are misleading and that the change should be made as soon as possible, so that the entire series can be properly dated. The longer the present erroneous dating is carried forward, the greater will be the ultimate confusion and the more difficult its rectification.

La citología vaginal humana en condiciones normales y patológicas; Su importancia para el diagnóstico y control terapéutico en ginecología. Por Ines L. C. de Allende, Doctora en medicina, jefe de la Sección endocrinología del Instituto de Investigación médica, Córdoba, Argentina, y Oscar Orías, doctor en medicina, director del Instituto de Investigación médica. Prologo del Prof. Dr. Bernardo A. Houssay, Paper. Pp. 313, with 165 illustrations. El Ateneo, Florida 310, Buenos Aires, 1947.

This book concerns human vaginal cytology in normal and pathologic states with the exception of cancer. It stresses and describes in some detail the endocrine aspect of vaginal cytology. The author is an experienced investigator in this field, having spent several years of study in the United States and in Argentina. The book is well written and contains a large number of drawings, color plates and graphs, which have been carefully selected and prepared.

The author describes the cytologic aspects of the menstrual cycle under seven phases as follows: (1) menstrual phase; (2) postmenstrual phase; (3) preovulatory phase; (4) ovulatory phase; (5) postovulatory phase; (6) progesterone phase, and (7) premenstrual phase, with diagrams illustrating the cytologic features of each.

Disorders of menstruation are discussed from the standpoint of the cytologic findings, frequently correlated with clinical and operative findings. Cornification curves are illustrated in graphic form, showing the rise in cornification associated with increasing production of the follicular hormone. Graphs are presented in cases of normal ovulatory cycles and in anovulatory cycles. In some cases of the latter, confirmatory surgical findings of persisting follicles coupled with an absence of ovulation and a continuous abnormally high cornification level are presented. Bleeding was shown to follow a drop in cornification, indicative of estrogen withdrawal.

Primary and secondary amenorrhea are discussed cytologically with the presentation of pictures of cells and graphs demonstrating cytologic deviations from normal.

Experimental results demonstrating effects on the amenorrheic curve with chorionic gonadotropin are presented.

Experimental production of cornification in vaginal smears in human castrates is shown following the administration of estrogen in its various forms, while the effect of the androgenic hormones and progesterone are also included.

This book should prove of value to endocrinologists, to those interested in fertility, to clinical cytologists and to pathologists. It demonstrates the value of well integrated cytologic studies in relation to the endocrine physiology of the ovary and of the menstrual cycle with their associated disorders.

Handbook of the Connecticut Cancer Society, Inc. (Branch of the American Cancer Society, Inc.). Fabrikoid. No pagination, with illustrations. Connecticut Cancer Society, Inc., 95 North Main St., Waterbury 14, 1946.

This is a handbook bound in a heavy paper cover simulating red leather and stamped in gold. The first item in the handbook is a brightly colored map of Connecticut by counties, showing those counties organized for field army and campaign purposes, those for campaign only and those unorganized. The state appears to be well covered by local anticancer groups. The publication is apparently derived in part from the American Cancer Society, of which a brief description is given followed by a chronological résumé of the state program and the state organization chart. After this pages are devoted to the personnel of the state society. There is a description of the committee on tumor study and of the Association of Connecticut tumor clinics, followed by information on the Division of Cancer Research of the State Department of Health. Then follows organizational material, such as how to organize a district, how to conduct an educational program, including the programs for youth and in industry; how to handle publicity, and how to carry out a service program in cooperation with the medical profession. A description is given of the information centers, and there are discussions of fund raising and financial reporting. There follows a page on what the layman should know about cancer, plus information on national research projects and official statistics. In the appendix is a list of printed material available from the American Cancer Society and the articles of association and the by-laws of the Connecticut Cancer Society. This is an excellent working kit for a working organization and might well

serve as a pattern for similar types in other states. In the absence of any price, it is to be presumed that sample copies may be procured free by making inquiry on official letterheads to the Connecticut Cancer Society at the address given.

Help Them Help Themselves. By Juliette McIntosh Gratke. Cloth. Price, \$2.50. Pp. 184, with illustrations. Texas Society for Crippled Children, 3703 Worth St., Dallas 1, Texas, 1947.

This book deals with the problems of the management of the child with cerebral palsy, in the fields of education, physical therapy, occupational therapy, speech therapy and general hygiene. In addition to a short review of the literature relating to some of the medical aspects of the problem of cerebral palsy, the book attempts to give some of the specific technics which may be employed in the training of the child. The most authoritative section of the therapies deals with speech training, in which the author is especially qualified. The book is of definite value to mothers who are attempting to train their children at home without benefit of medical direction, but may also be of value to some of the lay workers, nurses and therapists working with these children. The subject matter is illustrated by pictures, which, unfortunately, have suffered in clarity in reproduction. In all other manners, however, the book is well written and organized. Its cover is attractive, and its printing and paper are of good quality.

Although this book is by no means complete or, for that matter, authoritative, it is of great value for parents. It is written by the parent of a child with cerebral palsy, whose feelings have colored all of her writing. As a result, the book is warmly and clearly written and has a charm and style which makes it easy, interesting and valuable reading. For this reason alone, it is well worth recommending to parents.

Rheumatism and Soft Tissue Injuries. By James Cyriax, M.D., B.Ch., Physician-in-Charge of the Physiotherapy Department, St. Thomas's Hospital, London. Cloth. Price, \$9.50. Pp. 410, with 208 illustrations. Paul B. Hoeber, Inc., 49 E. 33rd St., New York 16, [1947].

There is no doubt about the qualifications of the author and his enthusiasm for his subject. His writings on this and related subjects are well known. His main thesis is mobilization as a therapeutic measure. He contrasts his theories with the theory of the bone setter who believes in subluxation of the vertebrae as the cause of practically all the ills that human flesh is heir to.

It is unfortunate that in the author's cases of subacromial bursitis roentgen treatment failed; this is not the experience of most American surgeons. It is unfortunate that so many of the photographs are not instructive or worthy of the space they occupy.

If the author rides his hobby a bit too often and attempts to explain too many conditions on the same theory, he may be excused because he has undoubtedly given so much personal attention to his patients that he has obtained good results where others have not.

His discussion of the manipulations of bone setters, osteopaths and chiropractors is well worth reading.

There is much material that is not related to the title of the book. The author includes much of the material that enters his daily practice.

Goethe als Patient. Von Dr. Wolfgang H. Veil, Direktor der Medizinischen Universitätsklinik Jena. Second edition. Paper. Pp. 303. Gustav Fischer, Jena 15, 1946.

Shortly before World War II Dr. Veil published an interesting medical study of Goethe and a second edition of this work, containing additional material is now available. The life history of Goethe has of course been painstakingly documented in the literature that has accumulated during the past hundred years, and Dr. Veil has made careful use of the source material in ferreting out the medical and psychologic items of significance. He starts his study with an analysis of the symptoms evident during the terminal episodes, which were apparently due to coronary thrombosis. He then carries through a readable account of the varied medical as well as psychologic episodes that occurred during the lifetime of his subject. The book will be of interest to the student interested in medical history, for it depicts the medical theory and practice of a time with which few medical men are familiar.

Textbook of General Surgery. By Warren H. Cole, M.D., F.A.C.S., Professor and Head of the Department of Surgery, University of Illinois College of Medicine, Chicago, and Robert E. Elman, M.D., F.A.C.S., Professor of Clinical Surgery, Washington University School of Medicine, St. Louis. Fifth edition. Cloth. Price, \$11. Pp. 1160, with 558 illustrations. D. Appleton-Century Co., Inc., 35 W. 32nd St., New York 1, 1948.

Now in its fifth edition, this teaching volume continues to improve. The general plan of the text remains unchanged. The advances made in surgery are specifically reflected. These include the lessons of the war and the growing knowledge of chemotherapeutic and antibiotic agents. Functional concepts of shock are presented with a clear understanding of the surgeon's point of view. Pleasing is the emphasis on the clinical, pathologic and physiologic aspects of surgery with relegation of technic to a minor status. The uses of the surgical tools—the hollow needle, the various fluids, chemotherapeutic agents, tubes, catheters and dressings, with which the interns and externs spend so much time—are well described. This is proper business for the student. There is time for major surgical technic later. The book continues to merit recommendation for teaching of medical students.

Annual Review of Microbiology. Volume I. Charles E. Clifton, Editor; Sidney Raffel and H. Albert Barker, Associate Editors. Cloth. Price, \$6. Pp. 401. Annual Reviews, Inc., Stanford University, California, 1947.

The vast amount of literature which has arisen recently on studies of micro-organisms and the attendant inability of the worker to keep abreast of all aspects of the field prompted initiation of this new series of reviews.

This volume and its successors are intended to fulfil the same function that "Annual Review of Biochemistry" and "Annual Review of Physiology" have in their respective fields. The type of review and manner of presentation are similar to those of the companion series.

The contents of this first volume include morphology and cytology of protozoa, antigenic variation in protozoa and bacteria, life cycle of malarial parasites, variation in phytopathogenic viruses, some aspects of the problem of growth factors for protozoa, bacterial metabolism, nitrogen metabolism, industrial fermentations, quaternary ammonium compounds, antibiotics, chemotherapeutic agents, medical and epidemiologic aspects of enteric infection, the Rickettsiae and respiratory viruses.

Topics in Physical Chemistry: A Supplementary Text for Students of Medicine. By W. Mansfield Clark, Ph.D., Sc.D., DeLamar Professor of Physiological Chemistry, the School of Medicine, Johns Hopkins University, Baltimore. Cloth. Price, \$10. Pp. 738, with illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

The first sentence in this unique book is a quotation from Clerk Maxwell: "For the sake of persons of different types, scientific truth should be presented in different forms and should be regarded as equally scientific, whether it appears in the robust form and vivid colouring of a physical illustration, or in the tenuity and paleness of a symbolical expression." The choice of this sentence to head the preface is highly significant, for Professor Clark is aware not merely of the facts of physical chemistry; he is keenly aware of the medical reader. He knows what aspects of physical chemistry the medical student is generally assumed to understand thoroughly but which many students understand only superficially. Hence he includes a lucid and unexpected chapter on the standard chemical balance and another on measurements of volume. The author understands what information is important to the medical student and medical investigator. Hence he gives a much more detailed treatment of such subjects as the equilibrium of blood electrolytes, the behavior of colloids and proteins and stereoisomerism than is found in the conventional texts on physical chemistry. Finally, the author is almost obsessed with the repugnance which most medical students manifest toward calculus. Accordingly, every important equation is handled by simple algebra. The one unavoidable use of calculus (Kelvin's "compound interest law of nature") is carefully explained in the first of the five appendixes. This remarkable appendix is excellently designed to make calculus simple and entertaining even to those who have a violent prejudice against it. A sample is the quotation, in the opening paragraphs, from Charles Slichter's "Science in a Tavern:" "Physics is the clanking, noisy part of mathe-

matics; chemistry is the smelly part of mathematics; biology is the musky part of mathematics." The author's robust humor bursts forth even in the appendix on definitions. Thus, among the rigorous definitions extended to the sixth decimal place and beyond, we find such things as the following: "Poise (noun). Unit of viscosity. See Viscosity. (Also: 'Poise is the art of raising an eyebrow instead of the roof.')

More clinical chemical measurements depend on color matching than on the determination of weights or volumes. Hence it is unfortunate that the author cannot analyze the magnitudes of error inherent in the visual and photoelectric comparators (colorimeters) with the same detail as is applied to the chemical balance and the volumetric pipet. The principles of the various types of instruments are, indeed, taken up with admirable clarity. Each of the numerous commercially available instruments, however, has its own limitations and eccentricities. Until we have an instrument as well standardized as the analytical balance, an exhaustive treatment of the comparator will be impossible in a book of this size.

In contrast to the usual text of physical chemistry, this book is so constructed that each chapter is complete enough to stand by itself. The student who wishes to do so may start in the middle of the book with the chapter on the blood electrolytes and follow the author's reasoning without difficulty.

The late Dr. Edwin Kepler once said: "The advance of medical science depends ultimately on the discovery of better ways of measuring things." All who share such a view will find Professor Clark's volume invaluable.

The Psychology of Behavior Disorders: A Biosocial Interpretation. By Norman Cameron, M.D., Ph.D. Under the Editorship of Leonard Carmichael, President, Tufts College and Director Tufts Research Laboratory of Sensory Psychology and Physiology. Boston. Cloth. Price, \$5. Pp. 622, with 2 illustrations. Houghton Mifflin Co., 2 Park St., Boston 7, 1947.

In his preface to this volume the author points out that "when we turn to psychiatry, we do not enter a new and a different world. The psychiatrist is still the physician, an organism working with the patient, another organism. They share and operate within a common social environment; they communicate by means of socially determined signs and sounds. These are the materials of medical practice as well as of psychology and psychopathology." From the beginning to the end of his book, Dr. Cameron practices what he teaches. His way of writing gives the impression of working with and sharing his ideas with the reader. He has attempted to avoid technical terminology as much as possible and explains it in everyday language whenever he introduces it. Each of the chapters are documented with case material and there are footnoted references to modern works on psychiatry and psychology. This is a textbook that provides interesting and useful reading for professional workers.

The opening sentences of the author's introduction clarify the title of the book: "The neuroses and psychoses, which together we call behavior disorders, are a natural part of our everyday environment. As adults all of us have dealings with neurotic and psychotic persons, and our children are being brought up among them just as we once were." In discussing behavior disorders as a national problem, the author tells his readers that "the problem of behavior disorders belongs, not alone to those who have them and those who directly treat or care for them, but to all of us." The first several chapters of this book are devoted to a description of the development of personality from uterine life to social maturity. These chapters include the development of the numerous mechanisms of defense which the author designates as basic adaptive techniques. There are eight chapters on various forms of mental illness and a final chapter on therapy.

The author approaches his subject matter from a biosocial point of view, which is a modification of the psychiatry of Dr. Adolf Meyer, which he points out "differs radically from the contemporary psychosomatic approach to the behavior disorders by breaking completely with the trends of mind-body dualism."

In addition to the discussions on personality and its disorders, there is much useful information in this volume which is not ordinarily found in standard textbooks on psychiatry.

Lehrbuch der Geburtshilfe und Gynäkologie. Herausgegeben von E. Anderes, H. Guggelsberg und Th. Koller. Band II: Lehrbuch der Geburtshilfe. Bearbeitet von P. Dr. H. Buess, et al. Herausgegeben von Prof. Dr. Th. Koller, Direktor der Universitäts-Frauenklinik in Basel. Erster Teil; zweiter Teil. Cloth. Price, 110 Swiss francs. Pp. 613, with 342 illustrations; 614-1323, with 343-711 illustrations. S. Karger, Holbelnstrasse 22, Basel.

This two volume textbook on obstetrics is the first to come out of a German-speaking country since the war. It was written by a group of nine obstetricians from the leading clinics in Switzerland under the editorship of Prof. Dr. T. Koller, the director of the University Frauenklinik in Basle. The two books could have been combined into a single volume, for they contain only 1,300 pages.

The first volume covers the history of obstetrics, the anatomy of the reproductive organs, including the hormonal glands which control them, the physiology of the reproductive function, normal reproduction and a discussion of some of the abnormal presentations and positions. The second volume deals largely with the pathologic complications of pregnancy and labor. The final chapter contains an excellent discussion of the anomalies and the pathologic conditions of the fetus and newborn.

The teaching in this textbook conforms with the accepted practice in the large German clinics prior to the recent upheaval in that country. Some major changes have been made, but they are in the minority. Clinical data presented in the various chapters by excellent tables and graphs are from the various Swiss clinics. However, the majority of the illustrations are from such well-known texts as Bumm, v. Jaschke, L. Seitz, Martius and Sellheim. Many new illustrations have been added.

Much can be said about the therapy and management of many of the obstetric complications. The great advances in the last decade which have altered the practice of obstetrics so favorably in this country have not had wide use on the continent. Analgesia and anesthesia are discussed briefly. Blood and plasma have not had wide use in obstetrics. The antibiotic drugs have probably not been available for widespread use. These major advances will undoubtedly find welcome acceptance in the near future.

The treatment of postpartum hemorrhage has not been brought up to date. The author still uses the aorta compressor and other heroic measures which have long been replaced by more rational therapy. Too great emphasis is placed on a long list of oxytocic drugs and cardiac stimulants of unknown value, and there is too little discussion of the management of the third stage of labor.

The illustrations, printing and format are excellent. There is no bibliography, although there are some references to authors in the text.

This textbook of obstetrics is a welcome contribution at this time and will undoubtedly become the standard text in German-speaking medical schools on the continent.

Retropubic Urinary Surgery. By Terence Millin, M.A., M.Ch., F.R.C.S., Surgeon, All Saints' Hospital for Genito-Urinary Diseases, London. Cloth. Price, \$7. Pp. 208, with 163 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

The author, a urologic surgeon of considerable experience, presents an inclusive monograph on the retropubic approach to various surgical diseases of the prostate gland. In particular, he details his experience with retropubic prostatectomy for benign prostatic hypertrophy. He brings to attention another surgical approach to the prostate, which since it was first described by van Stockum in 1909 has attained little recognition. In order to stress advantages of the retropubic operation the author tends to emphasize the shortcomings of all other approaches to the prostate. His enthusiasm for the operation which he describes is such that for the year September 1945 to September 1946 he employed the retropubic operation in 87 per cent of all cases of prostatic obstruction treated surgically. While it is true that there is probably no one else with experience in this type of surgery comparable to that of the author, even the majority of urologists would not agree with this selection of operation in so large a percentage of patients. The experience of the author is based on 375 cases, the first of which was in 1945.

Surgical anatomy of the prostate, types of instruments used, operative technic and essentials of preoperative and postoperative care are discussed. In most cases the author performs retropubic prostatectomy as a one stage procedure perhaps following preliminary drainage of the bladder with an indwelling urethral catheter. The author describes 18 cases in which this operation was employed as a second stage procedure following preliminary suprapubic cystostomy.

In this experience there have been relatively few postoperative difficulties or complications associated with retropubic prostatectomy. Incontinence does not occur if care is taken to avoid avulsion of the mucosa of the membranous urethra. Although the author has had only 1 case of persistent urinary incontinence, varying degrees of temporary leakage have occurred in a few cases. In a small number of cases there is some leakage of urine suprapubically following removal of the indwelling urethral catheter, which has been left in place postoperatively for only three days in most of his recent cases.

Chapters are devoted to enlargements of the subcervical and subtrigonal lobes, the fibrous prostate and the calculeous prostate, for the treatment of all of which the author presents certain advantages of the retropubic route. While his experience with radical removal of the malignant prostate is somewhat limited, he suggests that retropubic prostatectomy has certain advantages in cases of this type.

Surgical treatment via the retropubic approach of carcinoma of the bladder, traumatic rupture of the posterior urethra, prostatic abscess and stress incontinence in women is also discussed. Although one experienced in this field of surgery undoubtedly could find many uses for this approach, it appears reasonable that considerable time must elapse before final comparative appraisal of the retropubic approach can be forthcoming.

The author deserves great credit for his development of retropubic surgery, as little had been done in this field prior to the initiation of his efforts. He has brought to attention another approach to the prostate and region of the vesical neck which undoubtedly will prove to be useful in selected cases. The urologist now has the choice of four main approaches to the prostate gland, an opportunity which is stimulating, provocative and at times confusing.

Les syndromes douloureux de la région épigastrique. Par René-A. Gutmann. Tomes I et II. Bibliothèque des grands syndromes. Directeur: H. Roger. Fourth edition. Paper. Pp. 739; 766, with 1373 illustrations. G. Dolin & Cie, 8 Place de l'Odéon, Paris, 6^e, 1947.

This is the fourth edition of Dr. Gutmann's valuable work on painful syndromes of the epigastrium. Gutmann is one of France's most distinguished internists and gastroenterologists and has been in charge of the gastroenterologic clinic at the Salpêtrière for many years. His book is well written and beautifully illustrated with reproductions of 962 roentgenograms. The first 318 pages are on ulcer and its treatment. The only criticism of this section might be that in it Dr. Gutmann is too inclined to quote from the work of others and too reluctant to tell of his own experience and opinions.

The next section is on the earliest symptoms of cancer of the stomach; there are about 200 pages in this section. Dr. Gutmann wisely emphasizes the importance of studying not the late symptoms of cancer of the stomach but the early ones.

Section VIII is on the dyspeptic syndrome. Although today we realize that dyspepsia is not a good word, it may still be used for lack of a better one. In this section Gutmann discusses all sorts of conditions, such as aerophagia, cardiovascular disease, blood diseases, hyperthyroidism and hypothyroidism, asthenias and anorexias.

Unfortunately, Section IX, on nervous disorders, is only 20 pages long. In this the author discusses the "syndrome solaire" vagotonia and sympathicotonia and digestive troubles associated with psychoses.

Section X is on gastritis and duodenitis and the problem of hemorrhage. He discusses the important problem of hematemesis without a definite cause.

Section XI is on digestive troubles due to sensitization and digestive intolerance.

Following this are sections on digestive troubles associated with avitaminoses, syphilis, tuberculosis and deformations of the stomach and diaphragm; also postoperative syndrome. This is a particularly useful chapter.

Certainly, any one who can read French comfortably and would like to get an insight into the best French concept of gastroenterology should read through these two volumes.

Gutmann's preface to this fourth edition is very moving. First he gives homage to Professor Gosset, who has died. Then Gutmann tells a little of the years during the war, during which he had to hide, sometimes in a haystack, in order to save his life from those who wished to murder him. As he says, his time was lost because it was spent for the most part in attempts just to live and to keep out of the hands of the Gestapo. His son Claude was murdered by the Gestapo; also his nephew and his cousin. His brilliant pupil, Dr. Dulcy, was tortured and murdered. His assistant, Mademoiselle Dr. Rekis, was murdered, together with dozens of other students and assistants in the Salpêtrière.

Communicable Disease Control: A Volume for the Health Officer and Public Health Nurse. By Gaylord W. Anderson, A.B., M.D., Dr. P.H., Mayo Professor and Director, School of Public Health, University of Minnesota, Minneapolis, and Margaret G. Arnstein, R.N., M.A., M.P.H., Assistant to the Chief, Division of Nursing, United States Public Health Service. Second edition. Cloth. Price, \$5. Pp. 450, with 7 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

The second edition of this popular book will be welcomed by all who are familiar with the first edition. The volume, while intended for the health officer and the public health nurse, will be found useful by the student and practitioner. Divided into two parts, it contains discussions of many topics, including control measures, administrative agencies, role of the public health nurse, care of communicable disease cases at home and detailed discussions of many infectious diseases.

Dermatology for Nurses. By G. H. Perelval, M.D., Ph.D., F.R.C.P.E., Grant Professor of Dermatology, University of Edinburgh, Edinburgh, and Elizabeth Toddle, S.R.N., Sister in Charge, Department of Dermatology, Royal Infirmary, Edinburgh. Cloth. Price, \$4.50. Pp. 116, with 73 illustrations. Williams and Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

This compact little book contains a fund of practical information for the nursing care of patients with diseases of the skin. Only a few of the more common diseases are considered, but emphasis is placed on the principles of treatment which can be applied as well to the diseases which were omitted. Bandaging, bathing, the application of salves, lotions and the like are all fully considered and illustrated with photographs. In places, the writing could have been more simple.

The Scientific Paper: How to Prepare It, How to Write It, A Handbook for Students and Research Workers in All Branches of Science. By Sam F. Trelease. Cloth. Price, \$2. Pp. 152, with 8 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

This manual has gradually evolved from a small pamphlet into a useful work for those who wish to prepare a scientific paper. Added is a section on the use of the scientific library for research purposes. The recommendations follow, as no doubt they should, the principles of the Williams & Wilkins Company. The editorial staff of the American Medical Association is a little surprised that there is no reference whatever to the book called "Medical Writing," which covers somewhat the same ground with specific reference to medical contributions.

The American College Dictionary. Edited by Clarence L. Barnhart with the Assistance of 335 Authorities and Specialists. Cloth. Price, \$5. Pp. 1432, with illustrations. Random House, Inc., 457 Madison Ave., New York 22, 1947.

This is the newest dictionary on the American scene. A great number of scholars cooperated in its development and it has already had a considerable success. In the field of medicine and related fields, such as psychology and therapeutics, a considerable number of New York physicians have been helpful. The book is more modern than any other similar book. It includes considerable information not available in other dictionaries, such as rules for punctuation, proofreader's marks and notes on footnotes and bibliography.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MALARIA

To the Editor:—A missionary family expects to leave for Xingu Valley in Brazil this July. Malaria is endemic in this area. The family will consist of 2 adults, a 2 year old child, and a newborn infant. What are the suppressive and therapeutic doses of quinine, "atabrine" and chloroquine that I may recommend? Which of these would be more suitable for the children?
Lennard L. Weber, M.D., Philadelphia.

ANSWER:—Malaria due to *Plasmodium vivax* would be most frequently encountered in Brazil. Unfortunately, no curative agent for this type of malaria is available. Quinine, quinacrine ("atabrine"), chloroquine and chloguanide are all effective suppressive agents, however, and the choice of agent can be determined by relative toxicity and availability. Chloguanide is the least toxic agent, chloroquine next, and quinacrine and quinine the most toxic. Actually, quinine is not seriously toxic when compared on a weight basis with the other drugs, but in therapeutic doses, side reactions are frequent and unpleasant.

Neither chloguanide nor chloroquine has been used in infants or children sufficiently to establish dosage schedules which may be recommended. Chloroquine would probably be the drug of choice for infants and children because of ease of administration and relative freedom from serious toxic effects. Dosage should be adjusted to the age and weight of the child.

The following are the recommended dosage schedules for the four antimalarial drugs mentioned:

- Quinine:** Therapeutic dose, adults: 1.0 Gm. three times daily for two days followed by 0.6 Gm. three times daily for five days. Suppressive dose, adults: 0.6 Gm. daily.
- Quinacrine:** Therapeutic dose, adults: 0.2 Gm. given with 1.0 Gm. sodium bicarbonate in 200 to 300 cc. water every six hours for five doses. Following this, a dose of 0.1 Gm. three times daily for six days should be employed. Children 1 to 4 years: 0.1 Gm. three times daily for first day; then 0.1 Gm. daily for 6 days. Children 4 to 8 years: 0.2 Gm. three times daily for first day; then 0.1 Gm. twice daily for six days. Suppressive dose, adults: 0.1 Gm. daily. Children: 0.05 Gm. daily.
- Chloroquine:** Therapeutic dose, adults: 1.0 Gm. initially followed by 0.5 Gm. after six to eight hours and 0.5 Gm. on each of two consecutive days. Suppressive dose, adults: 0.5 Gm. weekly.
- Chloguanide:** Therapeutic in malaria due to *P. vivax*, adults: 0.1 Gm. three times daily for two to three weeks followed by 0.1 Gm. once or twice weekly for 6 months or longer. Therapeutic in malaria due to *Plasmodium falciparum*, adults: 0.1 Gm. three times daily for ten days. Suppressive in malaria due to *P. vivax*, adults: 0.1 Gm. Weekly. Preventive in malaria due to *P. falciparum*, adults: 0.1 Gm. twice weekly at three to four day intervals.

ALLERGY AND MYOPIA

To the Editor:—1. What are the best areas in California for patients with hay-fever and allergy? 2. What are other good places in the United States for sufferers from hay fever and allergy? 3. A 9 year old child has suffered from allergic rhinitis, sneezing, stuffy nose and throat breathing for three or four years. Within the past twenty months the child has become myopic. Is there an association between allergic rhinitis and myopia? Myopia is absent in both father and mother. Administration of diphenhydramine hydrochloride night and morning relieves symptoms of allergy but within the past year the visual acuity has slightly decreased.
M.D., New York.

ANSWER:—California is practically free from ragweed. Therefore, patients who are sensitive to ragweed will almost certainly be free of symptoms in any part of that state. The same holds true for all parts west of the Rockies, and there is little ragweed pollen in the state of Florida.

Those who are sensitive to grass pollen, on the other hand, will probably have symptoms in almost all parts of the United States. Those who are allergic to molds will have fewer symptoms in dry climates such as in Arizona and New Mexico. Those who are allergic to trees are usually specifically sensitive to certain trees and not to all. Avoidance of the special tree is usually sufficient for relief. For example, many suffer from mountain cedar pollen, which is especially found in certain parts of Texas and Arizona. Such sufferers obtain relief by moving away from these districts.

There is no known association between allergy and myopia.

UNDERWEIGHT

To the Editor:—What measures do you recommend for persons who are thin, underweight, apparently in good physical condition and who want to gain weight? Recently, I have had several such requests from my patients. After complete physical examination ruling out possible underlying medical cause, I put them on a high caloric diet (4,400 calories daily) rich in fats, a high potency vitamin combination, ten hours of bed rest, cessation of smoking and 20 mg. of thiamine hydrochloride intramuscularly twice weekly. At times, I have used the stuffing diet of Raffi and Brown. In several cases some progress (2 to 3 pounds [0.9 to 1.3 Kg.] weekly gain) was made; in others results were disappointing.
Herman Frack, M.D., Oak Park, Ill.

ANSWER:—Apparently you have already used the more obvious procedures such as (a) eliminating possible underlying medical causes, (b) feeding high caloric diets and (c) advising more rest. Possibly in those cases in which these measures proved ineffective, the patients did not really secure through their daily diet the calories aimed at. If they really ingested so many calories, these calories have to be accounted for somehow. Was any record kept of what and how much was really eaten? Personal impressions of how much has been eaten can be deceptive and erroneous. You might check this point by stating your need of the desired record for detailed study in order to find out what is wrong and thus get the record without seeming to tell the patient that he is mistaken about how much he eats. The consumption of diets with too large a percentage of fat should be discouraged.

There are psychological aspects of the matter worth considering. Are there any energy-rich foods that the patient greatly enjoys eating? The diet could be planned around these foods and others that are familiar to the patient. These foods should be presented in attractive, palatable form. Endeavor to make the eating of meals an enjoyable social function, instead of a time-consuming necessity of life. Teach the patient to forget his business and personal problems while he is consuming his meals. It is, of course, questionable just how much you can do, particularly with older persons, to change their attitude toward life by counsel and measures of this sort.

HYPOGLYCEMIA IN AUTO DRIVERS

To the Editor:—What is the best treatment for hypoglycemia (70 mg. of sugar per hundred cubic centimeters of blood). The patient is a truck driver, aged 45 (driving eighteen years). He states that at times the highway becomes blurred and he is afraid of "passing out."

V. M. McCartney, M.D., Monroe, Mich.

ANSWER:—1. Is the patient diabetic or epileptic or has he some other disease such as hyperinsulinism?

2. In the presence of blurred vision or premonitory symptoms of fainting, a diabetic or nondiabetic person has no business to drive an automobile until the cause is found and vision corrected.

3. Meals containing sufficient carbohydrate should be taken by both nondiabetic and diabetic persons at regular hours and no long periods without food should be allowed.

4. No diabetic person who takes insulin should drive an automobile without taking about 10 Gm. of carbohydrate every two hours between meals. Perhaps the safest plan would be to take 5 Gm. hourly on the hour. This may appear to be a small amount of carbohydrate, but the total quantity of carbohydrate burned by a diabetic or a normal person while relatively muscularly inactive is probably not more than 10 to 15 Gm. an hour.

5. No diabetic person should drive a truck unless he or she is under medical supervision every three months with a determination of visual acuity yearly. A good many diabetic persons drive automobiles thousands of miles a year, and one of the justifications for this is that in general their conduct of life is above the average of that of the general automobile licensee and that they realize their responsibility to the public, other diabetic persons, themselves and their own families.

6. Whereas it is wrong for any one to drive an automobile after drinking, it would be a heinous sin for a diabetic person to touch any kind of alcohol and then drive a car.

pH OF DIAPERS

To the Editor:—What is the optimal pH of diapers, and the range not irritating to babies?
M.D., New York.

ANSWER:—The baby diaper laundries have found that the optimal pH for the diapers is 5.5. This is slightly under the neutral of 7. The pH of 5.5 would insure that alkalinity has been counteracted or neutralized. Any variation of the pH between 5 and 6 is not thought to be the cause of skin irritation, and this slight variation is not significant.

TRANSFUSION IN ASTHMA

To the Editor:—What efficiency has blood transfusion in the treatment of bronchial asthma?
J. W. Hayden, M.D., Chicago.

ANSWER.—Blood transfusions have been used in the treatment of bronchial asthma from time to time. They probably have no specific effect in themselves, but they do contribute to increase of strength and resistance in cases of severe disease. This has been emphasized by Rackemann. It is especially valuable in the type of asthma which Rackemann has characterized as the "depletion" type. Persons with this type of asthma usually are of older age with low morale and poor resistance; they are apt to have associated complications such as chronic bronchitis, bronchiectasis and pneumonitis.

Cooke and his co-workers have shown experimentally that transfusion may relieve hay fever. That is, patients who have had good results from injections of ragweed extract have something in their blood which may favorably influence an untreated patient with hay fever due to ragweed. It should also be pointed out that there is some danger from blood transfusion aside from those dangers which not infrequently occur from this procedure. If blood from an allergic donor is injected into a nonallergic person, the recipient may become allergic to the particular allergen for a brief period of time, usually not more than a month. This was shown by Ramirez, Doerr and Duke. In Ramirez' case, a patient with pernicious anemia received a blood transfusion from a "horse-asthmatic" donor. A few days later, the recipient, while riding behind a horse, had an attack of asthma for the first time in his life. Duke noted a reaction after transfusion with the blood of a patient who had taken milk a short time previously.

CHRONIC ULCERS

To the Editor:—Is vitamin E taken orally of value in hastening the healing of chronic ulcers? A patient, a woman 82 years of age, has diabetic gangrene in both legs below the knees. She is now sugar free and the gangrene is controlled, but she has a large ulcer on each leg about 6 inches (15.2 cm.) above the instep that I have been unable to heal. Have you any suggestions?
M.D., Missouri.

ANSWER.—Vitamin E (alpha tocopherol) has been advocated by Shute and his co-workers for vascular thrombosis, but their evidence is meager and their results have not been duplicated anywhere else. The diabetic arteriosclerosis of the 82 year old woman will in all probability prevent the healing of the ulcers or the spontaneous elimination of gangrene and, if amputation cannot be considered, relief of pain and aseptic protective dressings are the only reasonable therapeutic measures.

DENTURES

To the Editor:—Is the use of such preparations as "fas teeth" and Wilson's "Corega" to keep dentures in place harmful in any way? What is their composition? Would they have any deleterious effect on leukoplakia in the mouth?
M.D., New York.

ANSWER.—The composition of Wilson's "Corega denture adhesive powder" is as follows: Each 100 Gm. is said to contain stercula gum 98.186 Gm., magnesium carbonate U.S.P. 0.274 Gm., methyl salicylate peppermint oil, menthol 0.068 Gm., and gum resin 1.472 Gm.

That of "fas teeth denture adhesive powder" is somewhat similar. Each 100 Gm. is said to contain 88.825 Gm. of stercula gum, 11.025 Gm. of sodium borate and 0.15 Gm. of peppermint oil. Nothing contained in these two or similar powders can be said to have a deleterious effect on leukoplakia of the mouth. The gel-like mass resulting when these substances combine with human saliva or other fluids and are retained for hours or days without a thorough cleansing of the dentures may, like the accumulations of food debris, aggravate oral tissues of low tone. This may be caused by a more rapid growth or increase of certain types of bacteria present in the mouth. Little or no research has been done either to prove or to disprove such a hypothesis. Well fitting dentures with

properly balanced occlusions of the teeth do not require the use of such preparations. Ill fitting dentures should either be refitted, remade or replaced.

In mouths with cleft palates or other form of serious malformation of the residual bony ridges, the moderate use of an adhesive powder may prove to be the only means of keeping the denture in place. Whenever these preparations are employed the patient should be informed that diligent hygienic care of the denture is absolutely essential.

DERMOGRAPHISM

To the Editor:—Is there any new treatment for dermographism?

Robert S. Srigley, M.D., Hollis, Okla.

ANSWER.—There are several varieties of dermographism, namely, red, white and black; it is assumed that the inquirer refers to red dermographism, which is the common variety.

The antihistaminic drugs are apparently of value in relieving this condition. Feinberg and Friedlaender (*J. Allergy* **16**:296 [Nov.] 1945) found that 50 mg. of diphenhydramine hydrochloride taken five hours, three hours and one hour before cutaneous tests were to be made would do away with whealing predicated on an inherent dermographic tendency of the patient but would not interfere with whealing due to an antigen-antibody mechanism. Baer and Sulzberger (*J. Invest. Dermat.* **7**:201 [Aug.] 1946) found that a subject exhibiting dermographism to a standard stimulus was relieved by the taking of 150 mg. of triphenylamine hydrochloride fifty minutes prior to the stimulus, but that this same amount had no influence on a fully formed dermographic wheal elicited by the same stimulus.

SULFONAMIDE COMPOUNDS

To the Editor:—What is the prevailing opinion regarding use of sodium bicarbonate in conjunction with sulfonamide compounds?

John R. Howitt, M.D., Hamilton, Ontario, Canada.

ANSWER.—The use of sodium bicarbonate in conjunction with the sulfonamide compounds is recommended so that the solubility of the sulfonamide drugs in the urine may be increased. The fluid intake in all patients who are taking sulfonamide drugs should be sufficient so that urinary output is at least 1,500 to 1,800 cc. during the twenty-four hour period. When the urinary output is adequate and the reaction of the urine is alkaline, the risk of renal complication from the sulfonamide drugs is greatly reduced.

PARALYSIS AGITANS

To the Editor:—What is the best treatment for Parkinson's disease? What can be added to belladonna to overcome dryness of the mouth? Is vitamin K of value? Is neostigmine ("prostigmin") of value?

Harry Hallarman, M.D., New York.

ANSWER.—The best form of treatment for Parkinson's disease (paralysis agitans) is use of one of the belladonna-like drugs, of which there are several. Scopolamine hydrobromide seems to be the most satisfactory in the largest number of cases. Drugs satisfactory for overcoming dryness of the mouth are not known. Dosage should be limited to the point where this manifestation of the drug is tolerable. Neither vitamin K nor neostigmine is of any known value in the treatment of this condition.

NO CANCER IMMUNITY FROM CARBON TETRACHLORIDE

To the Editor:—Do workers in a plant handling tetrachloride have immunity from cancer? Is there any known basis for such a statement?

M.D., Illinois.

ANSWER.—There is no basis for the statement that workers in a plant handling carbon tetrachloride have shown an immunity to cancer.

BASAL CELL CARCINOMAS

To the Editor:—In the issue of January 17, page 216, the answer to Dr. D. K. Adler's question on basal cell carcinomas stated that "no evidence is available to the effect that the incidence of cancer (excepting cancer of the skin) is greater in patients who have had basal cell carcinoma than in the general population." I wish to state that in persons who have had cancer of the skin, regardless of the histologic type (a) the frequency of cancer other than skin is much smaller and (b) the life expectancy is higher than in the general population. Statistical evidence is given in my papers (*Am. J. Hyg.* **34**:1-11, 1941, *Am. J. Med. Sc.* **199**:449-458, 1940). Rejection for standard insurance because of past history of basal cell carcinoma is not justified.

Sigismund Peller, M.D., New York City.

ESTIMATION OF PELVIC CAPACITY

Chairman's Address

WILLIAM F. MENGERT, M.D.
Dallas, Texas

There are five components of cephalopelvic disproportion: (1) size and shape of the bony pelvis, (2) size of the fetal head, (3) force exerted by the uterus, (4) moldability of the head and (5) presentation and position. Of these, only the first is susceptible to accurate measurement. Attempts to measure the size of the unborn fetal head have not met with much success. Moreover, such distortion can occur during the birth process that, even if accurate prelabor cephalometry were possible, the problem of cephalopelvic relations could not be reduced to mathematic exactitude. In addition, there remain the three imponderables, force of labor, moldability of the fetal head and method of presentation, about which there is no possibility of acquisition of knowledge before the event of labor. In passing, it may be noted that as our group studies the progress of labor among women with contracted pelves, we are more and more impressed that the force of labor is one of the most important factors, if not the most important, influencing outcome. There were times, and patients with unbelievably small pelves, demonstrating again and again the principle that successful vaginal birth depends largely on the driving force. Therefore, the problem of cephalopelvic disproportion must remain in the realm of the art of medicine rather than of its science. Although this conclusion is inescapable, we should not therefore assume a defeatist attitude.

Modern knowledge concerning the obstetric capacity of the bony pelvis may be said to have originated in 1861 with Litzmann,¹ since he was the first to offer acceptable numerical criteria of size. It must be emphasized that his work, and that of his predecessor, Michaelis, was concentrated on the pelvic inlet. It remained for Williams² in 1909 to provide numerical criteria for the outlet. Acceptable midplane criteria are not yet available, largely because it was an unknown territory and also because of relative inaccessibility to other than radiographic measurement. Nevertheless, the subject of midplane capacity has its pioneer. In 1930, Hanson³ of Stockton, Calif., devised an

instrument for the manual measurement of the distance between the ischial spines and by 1936 reported a series of measurements in 3,941 women.⁴ Despite this, and more recent publications, there are many who accord little significance to midplane contraction. Fascinating as the subject is, it is not the purpose of the present paper to concentrate attention on it. Rather, it is the purpose to consider evaluation of the obstetric capacity of the entire bony pelvis.

SUBJECTS

More than three years ago, the collection of information on cephalopelvic disproportion was begun at Parkland Hospital. At first, the pelves of selected patients, later those of all obstetric patients seen for the first time, were measured radiographically. Many difficulties, including the film shortage, intervened, so that to date our series numbers only 935 patients, of whom 592 have been delivered. The pelvis of each patient was measured manually and radiographically by obstetric-gynecologic residents, employing Snow's technic. The Department of Radiology of Parkland Hospital cooperated generously in making and processing the radiographs. The three planes were portrayed graphically⁵ and a prediction of the outcome of labor made. Since early intervention could afford no useful information, patients were allowed to progress to second stage pains with the membranes ruptured. A few were delivered electively by the abdominal route, because of previous cesarean section or because the pelvis was so decidedly contracted that a trial of labor was absurd. The results, including infant birth weight and the outcome of labor, were tabulated on punch cards for ready analysis.

METHODS

When it is desired to transport a large piece of furniture through a small hallway, the obvious preliminary is measurement of the height and width of the narrowest doorways. In like fashion, measurement of the anteroposterior and transverse diameters of a sufficient number of cross sections of the bony pelvic canal will provide knowledge of its capacities. Since the bony pelvic canal is not long, the symphysis being about 4.5 and the sacrum 10 cm. from tip to promontory, three cross sections, inlet, midplane and outlet, will suffice for estimation of capacity. Figures 1, 2 and 3 show outlines of these planes of a normal gynecoid pelvis obtained, as described in a previous publication,⁵ by shaping lead wire to the anatomic contours and correcting for minor variations. Except for

the outlet, the important diameters of each plane are the transverse and the anteroposterior. Since the outlet consists of two triangles with a common base and since the fetal head emerges through the posterior triangle, the posterior sagittal rather than the anteroposterior diameter of the outlet is employed. Six pelvic

Fig. 1.—Normal inlet. (Reproduced from Mengert, W. F., and Eller, W. C.: Graphic Portrayal of Relative Pelvic Size, *Am. J. Obst. & Gynec.* 52: 1032-1040 [Dec.] 1946.) The anteroposterior measurement is 11.5, the transverse 13.0 and posterior sagittal 4.0.

measurements, the transverse and the anteroposterior of each plane, will therefore provide all practical information necessary for evaluation of pelvic capacity.

Obviously, this necessitates use of radiographic methods, since it is otherwise impossible to measure the transverse diameter of the inlet of the living woman. It is not intended to inaugurate, or encourage existing, discussion regarding the relative merits of manual or radiographic measurements. Manual measurements are accurate for those diameters possible to reach. Also, any of the commonly and currently employed radiographic technics is accurate beyond our needs. Weinberg and Scadron⁶ measured the pelves of each of 100 patients within 0.1 cm. by four radiographic methods. The radiographic method currently employed

Fig. 2.—Normal midplane. (Reproduced from Mengert, W. F., and Eller, W. C.: Graphic Portrayal of Relative Pelvic Size, *Am. J. Obst. & Gynec.* 52: 1032-1040 [Dec.] 1946.) The anteroposterior measurement is 11.5, the transverse 10.5 and the posterior sagittal 5.0.

at Parkland Hospital was validated in two ways: by direct measurement with calipers and ruler during the

course of gynecologic operations and through check of the same patient by different observers. No error of more than 5 mm. was found. This is believed to represent a degree of accuracy exceeding the requirements of the situation.

In summary, it may be reiterated that method of measurement is unimportant. The interpretation and evaluation of pelvic capacity, after the measurements are obtained by whatever method, are the problems confronting the obstetrician. They can be solved only in conjunction with the experience gained through years in the delivery room. The opinion of a man who has not repeatedly followed the course of labor and does not know the extent of the forces concerned is valueless and worse; it is confusing.

INTERPRETATION

Many methods of evaluation of pelvic capacity were tried. At first, they consisted of fitting an outline cross section of the fetal head to the graphs of the various pelvic planes. Next, the sum of the posterior sagittal and transverse diameters was utilized as an index both for the outlet and midplane, with fair success. Nevertheless, some glaring discrepancies were observed. For example, a patient with the lower portion of the sacrum decidedly bent forward, and therefore with a very short posterior sagittal of the midplane, experienced an easy spontaneous labor. Review of the situation showed ample room anterior to the ischial spines. Moreover, this method was totally unsatisfactory for the inlet. The next logical step in the attempt to evaluate capacity was the utilization of the sum of the transverse and the entire anteroposterior diameter of the inlet or midplane. This gave more consistent results than other methods and led directly to the final and best method, calculation of the area of these two planes. At

Fig. 3.—Normal outlet. (Reproduced from Mengert, W. F., and Eller, W. C.: Graphic Portrayal of Relative Pelvic Size, *Am. J. Obst. & Gynec.* 52: 1032-1040 [Dec.] 1946.) The transverse measurement is 10.0 and the posterior sagittal 8.5.

first, areas were measured with a planimeter, carefully tracing the outlines and accurately recording the precise value in square centimeters. However, the actual figures are immaterial, since the relation of one pelvis to another, or of one plane to another, is the important consideration. Finally, the simple expedient of multiplying the transverse and the anteroposterior diameters and expressing the capacity of the various planes in terms of the product of these diameters was employed. Comparison of the two methods indicated no significant difference between them. The product of the two diameters of each plane is as satisfactory a measure of relative capacity as the more laboriously obtained measurement of the actual area. A norm can be established for each plane and its capacity expressed in percentage of normal. Thus, it is possible to compare not only one pelvis with another, but also two planes of the same patient. For example, a patient with an inlet capacity of 75 per cent of normal

6. Weinberg, A., and Scadron, S. J.: Value and Limitations of Pelvioradiography in Management of Dystocia, with Special Reference to Midpelvic Capacity, *Am. J. Obst. & Gynec.* 52: 255-263 (Aug.) 1946.

and a midplane capacity of 90 per cent is far better off obstetrically than a patient with the reverse conditions.

RESULTS

Average and Distribution of Measurements.—The essential pelvic measurements (table) include the transverse and the anteroposterior of the inlet and midplane and the transverse and posterior sagittal of the outlet. The transverse is accorded priority, since engagement generally occurs in this diameter of the inlet and internal rotation is hindered by a narrow midplane.

Fig. 4.—Distribution of 935 inlet and midplane capacities, expressed as areas (square centimeters). Roughly, the arrangement is linear from large to small. In other words, the inlet and midplane tend to vary together. Association of a large inlet with a small midplane, or the reverse, tends to be uncommon. The shaded area represents patients whose inlet or midplane capacities were 85 per cent, or less, of normal.

Moreover, with an adequate transverse diameter in any plane, there is seldom dystocia at that level.

The average values of the diameters as measured in 935 patients conform closely to accepted standards published by Stander.⁷ After the inlet and midplane

Essential Pelvic Measurements

	Accepted Standards	Average 935	Product, Ap. x Trans.
Inlet			
Transverse.....	13.0	12.5	145.0
Anteroposterior.....	11.5	11.6	
Midplane			
Transverse.....	10.5	10.3	124.9
Anteroposterior.....	11.5	12.1	
Posterior sagittal.....	5.0	4.5	
Outlet			
Transverse.....	10.0	10.6	
Posterior sagittal.....	8.5	8.8	

* There are six essential pelvic measurements, including the transverse and anteroposterior of each plane. The posterior sagittal of the midplane is included merely for interest.

products were obtained, the central tendency of each was calculated. For the inlet it was: average 145, median 146 and mode 143. For the midplane it was: average 124.9, median 126 and mode 121. The average values, rather than the median or mode, were utilized and 145 accepted as normal for the inlet and 125 as normal for the midplane. These figures represent 100 per cent, for each plane, respectively, and capacity is expressed in percentage in relation to them.

The entire series is illustrated graphically as a scatter diagram in figure 4. Broadly, the arrangement is linear, from large to small, indicating that inlet and midplane tend to vary together. In other words, association of a large inlet with a small midplane, or the reverse, is relatively uncommon. There are, of course, glaring exceptions to this rule.

Fig. 5.—Vaginal operations of necessity in 97 cases (inlet and midplane capacities) expressed as percentage of average. The midplane forceps operations tended to concentrate in the areas of less than average capacity, and all three craniotomies were performed in women with both inlet and midplane contractions. The numbers represent weight of infants in hundreds of grams; a horizontal line through a number represents labor more than thirty hours; M is midplane forceps operation; a square enclosing a number represents fetal death, and CR is craniotomy.

By a process of trial and error, it became obvious that 85 per cent of normal capacity of either inlet or midplane represented the border line between adequacy and contraction. The area of 85 per cent or less capacity is shaded in figure 4 and subsequent figures.

Fig. 6.—Graphic representation of data of cesarean section in 19 cases. Trial of labor, terminated by low cervical, extraperitoneal or cesarean hysterectomy, was permitted in patients with borderline pelvis. In most instances the trial was allowed to progress to second stage labor with the membranes ruptured. Elective abdominal delivery (without antecedent labor) was performed either in those women with indications other than cephalopelvic disproportion or in those with such frank contraction that a trial of labor was absurd. Plain circles represent cesarean section before onset of labor; PS is previous section, EP extraperitoneal section, CL classic section, LC low cervical section, EP extraperitoneal section and CH cesarean hysterectomy.

So far, little has been said concerning the outlet. It is doubtful whether outlet contraction exists as a sepa-

7. Stander, H. J.: Textbook of Obstetrics, New York, D. Appleton-Century Company Inc., 1945.

rate entity, unassociated with midplane contraction. This was evidenced in the present series by the fact that the intertuberosity diameter between the ischial bones was shorter than the interspinous in only two instances, and then the difference was negligible. In other words, the transverse diameter of the midplane is

Fig. 7.—Pelvis of M.P. (reproduced from Mengert, W. M., and Eller, W. C.: Graphic Portrayal of Relative Pelvic Size, *Am. J. Obst. & Gynec.* 52:1032-1040 [Dec.] 1946.) Although the inlet would appear to be barely adequate, its capacity is only 69 per cent of average.

commonly shorter than the transverse diameter of the outlet. There is no congenital anomaly or acquired disease which will narrow the tuberosities of the ischium without also narrowing the lower part of the innominate bones. In other words, there can be no serious outlet contraction without commensurate contraction of the midplane. Finally, much of what, in the past, we have termed outlet contraction actually is midplane contraction. When the vertex of the fetal

Fig. 8.—Midplane of patient of figure 7. (Reproduced from *Am. J. Obst. & Gynec.* 52:1032-1040 [Dec.] 1946.) Capacity is 72 per cent of average.

head has traversed a contracted midplane and is visible between the parted labia, the biparietal diameter is at least 7 cm. higher in the birth canal. This has been repeatedly demonstrated during the past few months by checking the progress of obstructed labors with lateral roentgenograms. They showed clearly that obstruction, when the vertex was on the perineum, was not at the ischial tuberosities, but at the level of the midplane, or above. This will be the subject of a forth-

coming presentation by one of the members of the department.

Operations of Necessity.—Figure 5 shows the distribution and outcome of vaginal operations of necessity among the 592 delivered women. There were seventy-three low forceps operations, twenty-one midplane forceps operations and three craniotomies. Low forceps operations of necessity were defined, for the purposes of this paper, as those performed after a two hour second stage arrest of labor. There was no time limit for midplane forceps operations. The majority of the low forceps operations occurred in patients anesthetized by means of caudal or spinal block. The midplane forceps operations tended to be concentrated in the areas of pelvic contraction, and all three craniotomies took place in women with combined inlet and midplane contractions.

Cesarean Sections.—Nineteen cesarean sections were performed among the 592 delivered women, an incidence of 3.2 per cent, or 1 in 31. This relatively high incidence of abdominal delivery was occasioned by the fact that the pelvis of most of the patients submitted to cesarean section were measured radiographically, automatically including them in the present series. In contrast, the incidence of cesarean section for the entire service during the same period of time was 0.55 per cent, or 1:181, representing twenty-three sections among 4,183 patients. Figure 6 shows the distribution of the nineteen cesarean sections among the subjects of this paper. These were performed on

Fig. 9.—Outlet of patient of figure 7 (reproduced from Mengert, W. F., and Eller, W. C.: Graphic Portrayal of Relative Pelvic Size, *Am. J. Obst. & Gynec.* 52:1032-1040 [Dec.] 1946).

18 women, two sections being done on the patient with the smallest pelvis in the series. It will be noted that elective abdominal delivery, without antecedent labor, was performed either in those women with indications other than cephalopelvic disproportion, or in those with obviously severe contraction. Moreover, since the trials of labor were continued into the second stage, and thus were not gestures, either extraperitoneal section or cesarean hysterectomy became the operation of choice on conclusion of the trial.

The pelvis of the patient M. J., with the most pronounced contraction in the series, has been portrayed graphically elsewhere.⁵ It is worth reproducing (figs. 7, 8 and 9) here for several reasons. Morphologically the pelvis is anthropoid in type and illustrates the principle that transverse narrowing is serious. For example, although the inlet would appear to permit passage of an average head, it had but 69 per cent of capacity. The midplane appeared to be less fit to permit passage of the fetal head, but its capacity actually was 72 per cent of average. This patient submitted to elective cesarean section in two successive pregnancies. This case is in contrast with that of H. L. J.

(figs. 10 and 11). The inlet appears to be small, but had 82.5 per cent of average capacity. There was only 75 per cent of average midplane capacity, but sufficient room anterior to the spines to permit passage of the head in a transverse position. The first stage of labor lasted 23 hours, the second one hour, and a living child weighing 2,912 Gm. was born spontaneously. These 2 patients illustrate quite well the comparison of pelvis and planes when capacity is expressed in terms of per cent of average.

Mortality.—There was no maternal death in the series. There were 26 fetal deaths, of which 12 were due to causes including anomaly, prematurity, syphilis and accidents of pregnancy. There were 14 fetal deaths related to cephalopelvic disproportion or which were unexplained (fig. 12). Causes included tentorial tear and scalp injury with hemorrhage and craniotomy. There was a tendency for fetal deaths to be concentrated in, and toward, the areas of less than average pelvic capacity.

Fig. 10.—Although this inlet looks small, its capacity is 82.5 per cent of average.

COMMENT

Radiographic pelvic measurement is not feasible for all pregnant women. Moreover, it is unnecessary when manual methods indicate an obviously adequate pelvis. Therefore, an attempt was made in a previous publication⁸ to enumerate criteria of suspicion indicating the necessity for employment of radiographic methods. They should be employed in the presence of any one of the following observations:

- A. History
 1. Difficult labor, especially midforceps delivery
 2. Unexplained stillbirth
- B. Palpation
 1. Prominent ischial spines
 2. Sacral deformity (any, but especially forward angulation)
- C. Manual mensuration
 1. Inlet
 - (a) Ability to touch sacral promontory on vaginal examination.
 - (b) External measurements below average; i. e., interspinous 23 cm. or less, intercrystal 26 cm. or less and external conjugate 17 cm. or less
 2. Outlet
 - (a) Bisischial 8.5 cm. or less
 - (b) Sum of bisischial and posterior sagittal 15.0 cm. or less
- D. Nonengagement of fetal head at term in a primigravida

8. Eller, W. C., and Mengert, W. F.: Recognition of Midpelvic Contraction, *Am. J. Obst. & Gynec.* 53: 252-258 (Feb.) 1947.

There are some who will insist that harm, as a direct result of failure to perform cesarean section, must inevitably accrue to some women. There can be no disagreement with this view. There were two vesicovaginal fistulas resulting, respectively, from craniotomy and a serious midplane forceps operation. Less

Fig. 11.—Midplane of patient of figure 10. Although the capacity is 73 per cent of average, there is sufficient room anterior to the spines. After twenty-four hours of labor, the patient was delivered spontaneously of a 2,912 Gm. living child.

obvious, but commoner, was puerperal pelvic cellulitis or, as observed clinically, prolonged morbidity. When the pelvic cellular tissues are compressed and squeezed between the fetal head and the maternal bones, and thus rendered partially or totally ischemic for pro-

Fig. 12.—Fourteen fetal deaths related to disproportion or which were unexplained. All fetal deaths in term-sized infants, known to be alive at the onset of labor, whose mothers were free of diseases such as syphilis and eclampsia, are included here. Note the tendency to concentrate in and toward the areas of less than average pelvic capacity. (NN is neonatal; IP is intrapartum; Cr is craniotomy.)

tracted periods of time, they may be readily victimized by invading bacteria. Following difficult labor, there is generally endometritis. Although of short duration

and disappearing spontaneously, the endometritis institutes infection in the devitalized parauterine and paravaginal cellular tissues because of lowered resistance.

On the other hand, it was amazing how many seemingly impossible cephalopelvic disproportions disappeared under the driving force of the uterus. The resulting spontaneous labor was followed by normal and speedy convalescence. Conversely, when the uterine forces were poor, pelvic contraction of minor degree sometimes offered an insurmountable obstacle to the progress of labor.

SUMMARY

Of the five components of cephalopelvic disproportion, only one, the bony pelvis, is susceptible to accurate measurement. Next to pelvic size, perhaps the most important component affecting the outcome of labor is the driving force of the uterus.

The subject of cephalopelvic disproportion was actively studied at Parkland Hospital through the mediums of radiographic measurement and graphic portrayal of pelvic planes. It was observed that the best index of either inlet or midplane capacity is the product of the transverse and the anteroposterior diameters. This necessitates radiographic measurement, since the transverse diameter of the inlet cannot otherwise be measured in the living woman. The manner of obtaining measurements is unimportant, since any acceptable method offers accuracy within a few millimeters. The problems confronting the obstetrician are, therefore, interpretation of measurements and evaluation of capacity, not the making of measurements.

After determination of the index of average inlet or midplane capacity by multiplication of the transverse and the anteroposterior diameters, a given pelvis could be compared with the average in terms of percentage.

In general, inlet and midplane tended to vary together. In other words, association of a large inlet and a small midplane, or vice versa, was relatively uncommon. There were, of course, glaring exceptions to this rule.

Through experience gained with the method, it was learned that 85 per cent of average capacity represents a reasonable borderline between adequacy and contraction.

2211 Oak Lawn Avenue (4).

Hemoglobin Values.—An anemia may be defined as a reduction in the hemoglobin of the blood below the normally accepted values. Our own conclusions at the University of Michigan, after an extensive study of many normal persons, is as follows: (1) If 100 per cent is accepted as 15.6 Gm. of hemoglobin per 100 cc. of blood, the lower limit of normal for adult males is 13.0 Gm. or 83 per cent, and for females it is 12.0 Gm. or 77 per cent; (2) ordinarily patients do not experience the usual symptoms of an anemia unless the hemoglobin falls to the vicinity of about 11 Gm. or 70 per cent, or lower; (3) the physiologic anemia of pregnancy, due entirely to dilution of the circulating blood, may lower the hemoglobin of a pregnant woman to 64 per cent under normal conditions. Hence a true anemia of pregnancy is not present unless the hemoglobin is below this figure.—Sturgis, Cyrus C., M.D., *Official Journal of the Interstate Postgraduate Medical Association—Postgraduate Medicine*, June 1948.

STUDIES OF HEMOPHILIA

I. The Control of Hemophilia by Repeated Infusions of Normal Human Plasma

BENJAMIN ALEXANDER, M.D.
and
GRETA LANDWEHR, B.S.
Boston

No method of therapy has hitherto been devised which has proved effective in the long-continued control of hemophilia. The purpose of this paper is to report the effects of repeated infusions of normal plasma on the delayed blood coagulation and on the hemorrhagic tendency of this disease. Our observations on patients treated over a period of ten to twenty months indicate that this therapeutic approach provides a basis for amelioration of the bleeding tendency with significant rehabilitation of such patients.

Most observers¹ have agreed that the addition of whole blood, plasma or certain plasma fractions to hemophilic blood results in the prompt reduction of the clotting time. In vivo the effect is said to last from two to six days.² This property of normal blood probably explains the effectiveness of transfusion in controlling acute hemorrhage in this disease.

Whether or not the hemorrhagic phenomena in hemophilia are referable entirely to delayed blood coagulation, it would seem desirable to maintain the clotting time of hemophilic blood at relatively normal levels. The difficulties inherent in repeated blood transfusions for this purpose over a prolonged period are obvious. The use of plasma or of plasma fractions, on the other hand, is far less difficult.

Despite some progress made in the concentration and isolation of the antihemophilic component of plasma,³ potent fractions are not yet available for general clinical use. Until such time, or until another agent is discovered which will correct the abnormal coagulation of hemophilic blood, prophylactic therapy must consist of the use of plasma.

In 1942 Johnson⁴ reported the successful management of 1 patient with hemophilia by means of lyophilic human plasma administered weekly for three months, a period which is inadequate to evaluate any therapy accurately in view of frequent remissions and exacerbations of the hemorrhagic phenomena in this disease.

From the Medical Research Laboratories, Beth Israel Hospital, and the Department of Medicine, Harvard Medical School.

Furthermore, Munroe and Jones⁵ described a patient whose disease, after many blood and plasma transfusions, became increasingly refractory to their effects. Refractoriness also to the antihemophilic property of certain plasma fractions has been described.⁶ Since the beneficial clot-promoting effects of blood or plasma would appear promising in the prophylactic management of hemophilia, it is of the utmost importance to determine whether such refractoriness commonly develops consequent to their frequent use over a long interval.

In view of the evanescent effect of any single plasma infusion it must be given more often than once a week in order to maintain a reduced clotting time. For this reason, our patients were given plasma three to four times weekly for ten to twenty months. Laboratory and clinical observations made during this time are here presented.

PROCEDURE

Four subjects were treated:

CASE 1.—T. K., aged 24 years, had group B, Rh-negative blood, with an original clotting time of sixty-five to ninety minutes. One of his mother's brothers died of severe bleeding, and one of his own brothers who died at the age of 6 months was thought to be a bleeder. From the age of 1½ years there were numerous hemorrhages into joints, muscles, genitourinary tract and from gums. The patient was frequently incapacitated, with innumerable hospital admissions. He was studied for years at another hospital, where weekly plasma therapy for two years was ineffective in preventing hemorrhages. He was never employed steadily because of frequent hemorrhages.

During the present study the patient received two hundred and six infusions of 150 cc. of plasma three times weekly for eighteen months. For another one and one-half months, because of a hemorrhagic episode described later, the patient received 100 to 150 cc. of plasma daily or twice daily. Thereafter he was given plasma therapy three times weekly. Throughout the observation period of twenty months there were several lapses in therapy of four days to one month when the patient left town on holidays. Total plasma injected was approximately 38 liters.

CASE 2.—I. G., aged 28, had group O, Rh-positive blood, with an original clotting time of one hundred and twenty minutes. One brother died in infancy of hemorrhage. The patient had experienced bleeding episodes since the age of 6 into joints and muscles, from mucous membrane and into the genitourinary tract. He was severely crippled and incapacitated, and had been studied and treated for years at another hospital.

He received two hundred and seventy infusions over nineteen months, totaling approximately 41 liters, as follows: 150 cc. three times weekly for nine months; four times weekly for one and one-half months; daily for one and one-half months; four times weekly for five and one-half months, and three times weekly thereafter.

There were occasional short lapses (four to five days) for experimental purposes and one (ten days) because of illness (episode of jaundice) preventing his return to laboratory for scheduled treatment.

CASE 3.—R. R., aged 17 years, had group A, Rh-positive blood, with an original clotting time of one hundred and eighty minutes. There was a negative family history. The patient had had hemorrhages since early infancy, into joints mostly, and from deciduous teeth. He was hospitalized ninety times and was considerably crippled, unable to attend school.

This patient received one hundred and seventy-three infusions of 180 cc. three times weekly for thirteen months, totaling about 31 liters. There was one four day lapse, when icy road conditions prevented the patient from coming to the hospital for scheduled treatment.

CASE 4.—C. R., aged 8 years, had group O, Rh-positive blood. The family history was positive for hemophilia. The patient had had hemorrhages since early childhood into joints and muscles, interfering seriously with school work. His physical activity was restricted. He was first seen by us because of severe hemorrhage into the gastrocnemius muscle.

He received one hundred and eleven infusions of plasma, 100 cc. three times weekly for ten months. There was one lapse of two and one-half weeks when the patient was confined to his home because of chickenpox.

The plasmas were prepared as follows: 250 cc. "pyrex" glass centrifuge bottles containing 25 cc. of 2.5 per cent sodium citrate solution were filled with blood from normal subjects,⁷ capped and centrifuged⁸ for fifteen to twenty minutes at 2,000 revolutions per minute.

The supernatant plasma was removed with a syringe and placed, in amounts of 100, 150 or 180 cc., into a dry Fenwal flask. The bottled plasma was then quickly frozen and stored in the frozen state⁹ at 10 F. Sterile technic was used throughout. Bloods with positive serologic tests for syphilis were excluded.

Some flasks contained plasma of two to three blood groups; most, however, contained plasma of only one type. No attempt was made to give plasma of homologous type, although for the first six months all donors were typed. Since no reactions could be attributed to incompatibility, typing was discontinued thereafter.

Immediately prior to administration the frozen plasma was thawed in a water bath at body temperature or less, filtered quickly through a stainless steel 150 mesh filter into another Fenwal flask, and administered intravenously in five to ten minutes with a Fenwal set.

Determinations of the coagulation time, by a modification of the Lee and White method,¹⁰ were frequently made immediately before, immediately after and twenty-four, forty-eight and seventy-two hours after administration of plasma.

Occasionally, plasma was withheld in order to permit observation on the height to which the clotting time would rise and to reevaluate quantitatively the clot promoting effect of plasma in vivo and in vitro.¹⁰

LABORATORY OBSERVATIONS

The infusion of plasma was always followed, almost immediately, by a pronounced drop in the coagulation time to normal or near normal limits.¹¹ The clotting time remained low during the first twenty-four hours, increased gradually during the subsequent day and, unless another plasma injection was given, returned to its previous level within seventy-two or more hours (figs. 1 and 2). This pattern of reaction was uniform for 3 of the subjects who were thus studied. Variations in coagulation time were seen in the same patient twenty-four, forty-eight and seventy-two hours after any single plasma infusion, and a difference was noted from patient to patient in the average clotting time twenty-four, forty-eight or seventy-two hours after administration of plasma. The difference could not be correlated with the original clotting time before plasma therapy.

7. Dr. Mark Lesses, Director of the Blood Bank, Harriet Sheffren, in charge of the Volunteer Blood Donors, and volunteer blood donors cooperated in making blood available for this purpose.

8. Since the antihemophilic principle of plasma is labile, particularly in whole blood,¹² most of the blood was processed within one-half hour after withdrawal.

9. Under such conditions, antihemophilic potency remains unaffected for at least five months.

11. The normal range for the clotting time was considered to be 4-11 minutes.

5. Munroe, F. L., and Jones, H. W.: The Detrimental Effect of Frequent Transfusions in the Treatment of a Patient with Hemophilia, *Am. J. M. Sc.* 206:710, 1943.

6. (a) Pohle, F. J., and Taylor, F. H. L.: The Coagulation Defect in Hemophilia: The Effect in Hemophilia of Intramuscular Administration of a Globulin Substance Derived from Normal Human Plasma, *J. Clin. Invest.* 16:741, 1937; (b) The Coagulation Defect in Hemophilia: Studies on Refractory Phase Following Repeated Injections of Globulin Substance Derived from Normal Human Plasma in Hemophilia, *ibid.* 17:779, 1938.

In none of the patients did the disease become refractory to the effects of normal plasma. There was, furthermore, no evidence that by maintaining the coagulation time at levels more closely approximating normal, the underlying defect in blood coagulation was

Fig. 1.—Effect of repeated infusions of normal human plasma on clotting time of hemophilic blood. The numeral in parentheses represents the number of determinations of the clotting time at the designated interval. The points on the curves represent the averages of these determinations.

any less at the end than at the beginning of the therapeutic regimen described. The over-all effect of repeated infusions of plasma is indicated diagrammatically in figure 3. Despite peaks in clotting time reached immediately before each administration of plasma, the average clotting time was greatly reduced. As little as 1 cc. of intravenously administered normal plasma hastens the coagulation of hemophilic blood. The duration of this effect varies with the dose (fig. 2; table 1). Ten cubic centimeters may lower the clotting time to relatively normal limits, but the effect lasts for a shorter interval than when 100 or 150 cc. are used.

Fig. 2.—The effect of varying amounts of normal plasma administered intravenously on the coagulation time of hemophilic blood.

Larger amounts produce a more sustained action, but the prolongation of the effect is not directly proportional to the dose. The effects of 50 or 100 cc. of plasma are at times practically indistinguishable from the effects of 10 cc., and the difference between 750 and 230 cc. is slight. Intramuscularly administered plasma appears to be far less effective in hastening the coagulation of hemo-

philic blood (table 2). As much as 30 cc., 15 cc. injected into each buttock followed by five minute massage of the injection site, failed to reduce the clotting time as much as 1 cc. given intravenously. The slight effect which was obtained appeared in one-half to one hour after injection, whereas intravenous plasma acts almost immediately. It is noteworthy that plasma, even in amounts of 650 to 750 cc., does not reduce the clotting time much below the upper limit of normal. Most often it ranged, immediately after infusion, between eleven and fifteen minutes (fig. 3).

CLINICAL OBSERVATIONS

Case 1.—The clinical course of all the patients during this period of prolonged prophylactic therapy was strikingly improved. Patient 1 was free of major

hemorrhagic episodes throughout the time that he received plasma regularly despite greatly increased activity (swimming, bowling, baseball, basketball, gymnastics, squash, running, horseback riding). In no instance was there more than localized ecchymosis even following types of trauma which had hitherto resulted in moderate to severe hemorrhage. Hemostasis in dental care involving scraping the gums was greatly simplified. For the first time, the patient was able to do sustained remunerative work for one and one-half years. This patient experienced four significant hemorrhagic episodes. The first occurred five days after a plasma infusion, when, while on a short holiday (five days) the patient fell down some steps, incurring severe trauma to arm and leg. The second hemorrhage, hematuria, developed after four days without plasma, again while the patient was traveling. This subsided within one week after plasma therapy was resumed.

A third episode, oozing from an extensive pyogenic ulceration of the buccal mucosa, which persisted despite plasma therapy, ceased dramatically after the first of several penicillin injections administered in doses of 200,000 units with each plasma infusion for one week. The ulcer cleared promptly. The fourth episode

occurred spontaneously when the subject was again on a month's holiday; incapacitating hemarthroses developed five days after the last plasma and were followed later by hematuria. Hematuria persisted for six weeks despite several whole blood transfusions and infusion of plasma daily or twice daily, each of which reduced the coagulation time to normal range. The addition of penicillin to some of the plasmas was also ineffective in instituting hemostasis.

Case 2.—The second subject had suffered extensive crippling as a result of repeated hemarthroses and hemorrhages into the gastrocnemii. This patient, likewise, has been rehabilitated. For the first time in his life he has been able to do some remunerative work in his profession (commercial artist). Despite his incapacitation, he has been able to travel 80 miles (129 kilometers) to and from the hospital for his treatments.

During the period of study this subject had four hemorrhagic episodes. Two hemorrhages, one in an elbow and one in a knee, occurred after plasma had been withheld for four days for experimental purposes; the third, an ileofemoral hemorrhage,^{1c} began during a week end about sixty hours after a plasma infusion, and required hospitalization. For these reasons, therapy was changed from three to four infusions weekly. The fourth episode occurred while the patient was without plasma for ten days when, because of jaundice, he was advised to remain at home. All except the ileofemoral episode were mild to moderate in severity and lasted about one week while plasma therapy was continued.

Because it was felt, after one year's observation, that this patient's hemorrhagic tendency could be controlled by repeated infusions of normal plasma, a bilateral open tenoplasty of the achilles tendons was performed to overcome abnormal plantar flexion consequent to old hemorrhages into the gastrocnemii. It was felt that this physical handicap interfered with the patient's gait and resulted in undue strain on the knees, thus predisposing these joints to trauma. Seven days after an uneventful operation the wounds began to ooze despite daily plasma infusions which reduced the clotting time to relatively normal levels. At this time, the patient

was slightly febrile and the wounds had partially separated. Because infection was suspected, the patient was given full doses of sulfadiazine and 300,000 units of penicillin with a daily plasma infusion for one week. Following the first dose of penicillin bleeding ceased and recovery was uneventful, the wounds healing by secondary intention. One hundred and fifty cubic centimeters of plasma was given daily for forty-two days and every other day thereafter. The operative result was good; the patient's gait is now greatly improved.

Case 3.—The third subject has also been much more active physically and socially, indulging in baseball, touch football, hunting, bowling, etc., for the first time in his life. He is experiencing his most sustained interval of uninterrupted school attendance, broken only by a severe infection of the respiratory tract requiring hospitalization and by one hemorrhage, described in the next paragraph. He, too, travels 80 miles three times weekly to receive plasma.

Despite many incidents of trauma there have been only three significant hemorrhagic episodes with no history of antecedent trauma. The first, sixty hours after a plasma infusion (over a week end) occurred into a knee and subsided within four days without requiring bed rest. The second, also into a knee, began about eighty hours after the last infusion of plasma (the patient failed to come in for his scheduled infusion of plasma because of icy road conditions). Incapacitation lasted about ten days, during which time the patient continued to receive plasma issued by us and administered daily at home by his local physician. The third hemorrhage, also into a knee, began seventy-two hours after a plasma infusion (over a week end) and subsided within three days while plasma therapy continued.

Case 4.—This subject has also been relatively free of significant hemorrhagic episodes despite greatly increased physical activity and many traumatic episodes, one occurring on a day when the patient was scheduled to receive plasma, consisting of a deep

Fig. 3.—The over-all reduction in coagulation time induced by regularly administered normal plasma to persons with hemophilia. The areas enclosed by the rectangles represent the clotting time over the study period, integrated from the curves in figure 1.

long laceration of the hand requiring hospitalization. Restriction of play at home and in school have been largely eliminated.

It is practically impossible to record all the minor hemorrhages and ecchymoses which a hemophilic patient ordinarily experiences during the course of his disease. These are so many and frequent that the usual patient pays little attention to them. During the course

of plasma therapy the subjects were unanimous in their opinion that they experienced markedly fewer minor hemorrhagic phenomena despite a pronounced increase in activity. With every lapse in plasma therapy the lesser hemorrhagic phenomena reappeared.

Control of the disease, as well as the disease per se, required numerous social and psychiatric readjustments. These will be described in a separate communication.¹²

Ten reactions to plasma were observed, an incidence of 1.2 per cent. Six were minor, characterized by urticaria or momentary faintness and giddiness. One, moderately severe, occurred early in the course of the study after the administration of a specimen which was not previously filtered.¹³ Of the remaining three one was severe, associated with drop in blood pressure, dyspnea, distressing cough and severe headache, and two were moderate, producing chills, malaise, and transient fever. The incidence of reactions was no greater toward the end than at the beginning of the period of therapy.

One subject (I. G.) experienced insidiously developing jaundice associated with malaise, severe anorexia, mild epigastric distress and discomfort in the right upper quadrant. Physical examination revealed no abnormality except for jaundice and definite tenderness to palpation and percussion in the right upper quadrant and over the right lower costal border anteriorly. The icteric index was 67. After ten days at home, sixteen days after onset, the patient returned for plasma therapy, definitely improved and free of symptoms. At that time, his icteric index was 36, and three and one-half weeks later it was 14. We consider this a probable episode of mild "homologous serum jaundice."

COMMENT

Although transfusion with blood or plasma is generally accepted as being effective in the treatment of acute hemorrhage in hemophilia, no therapeutic plan has until now been devised which will control the hemorrhagic tendency over a prolonged period. On the basis of our observations we believe that frequent infusions of normal plasma are effective in the control of this disease.

There is considerable uncertainty as to whether the bleeding tendency of hemophilia is related solely to the delayed coagulation or also to some other factors such as disturbances in function of capillary and larger vessels in response to trauma. The beneficial effects of normal blood or plasma may also be referable to other factors besides their property of hastening the coagulation of hemophilic blood.

We have noted, in accord with numerous other observers, that bleeding may continue in persons with hemophilia when coagulation times are reduced and maintained only slightly above normal levels. After bleeding has proceeded for some time, reduction to relatively normal clotting time may, in some cases, fail to induce prompt hemostasis. This may be related to hemophilia per se or to local infection, as is suggested by the dramatic response to penicillin¹⁴ in cases 1

and 2. Continuation of bleeding despite reduction in clotting time should be differentiated from initiation of new hemorrhages. In the latter the effect of vasoconstriction of the injured blood vessel exerts its fundamental role in the over-all hemostatic mechanism.¹⁵ After several hours this important vascular reaction operates no longer.

Experience obtained in the use of heparin for delaying coagulation of blood in the treatment or prevention of phlebothrombosis and embolism indicates that a clotting time of between fifteen and twenty minutes is a relatively safe range within which untoward hemorrhagic phenomena are unlikely to occur,¹⁶ although exceptions are occasionally encountered. Retarding coagulation by heparin to two to three times the normal is regarded as innocuous except in cases of active bleeding or within three hours following surgery. Even immediately after infusion of plasma the coagulation time of hemophilic blood is at best in the upper limits of normal, or, more often, slightly above normal (fig. 1). Under such conditions the person with hemophilia may be compared with a heparinized person having a similar coagulation time. That the latter will exhibit persistent bleeding if heparinization takes place too soon after surgical treatment or that he may experience spontaneous hemorrhage is perhaps of significance in explaining some of the hemorrhagic phenomena seen in hemophilia despite transfusions with blood or plasma.

Of fundamental importance is the question: Is the hemophilic patient with a clotting time of ten to twenty minutes less prone to hemorrhage than one with a clotting time of thirty to one hundred and eighty minutes? The proved efficacy of blood or plasma transfusion in the therapy of acute hemorrhage in hemophilia supports an affirmative answer. The positive correlation between bleeding tendency and delayed blood coagulation induced by heparin also supports this view.

On the basis of experience with heparin it would seem desirable to maintain the clotting time of hemophilic blood at least below twenty minutes. As can be seen from figure 2 this can be done only by the administration of about 10 cc. of plasma every eight hours, 150 to 180 cc.¹⁷ every twenty-four to thirty hours, or disproportionately greater amounts every forty-eight hours. The first method is not practical; the third seems inordinately wasteful of plasma in view of the rapid disappearance of the clot-promoting effect in vivo (fig. 2¹⁸). The dosage and frequency of administration which we employed were considered the most practical under the circumstances, although it was realized that the coagulation time would, and often did, exceed twenty minutes and that hemorrhage might accordingly ensue.

The isolation of thromboplastic and other clot-promoting elements from various biologic materials has been attempted. Excepting some derived from human plasma their intravenous use may be dangerous.

17. Less would be necessary for children, probably proportionate to the blood volume.

18. Alexander, B.: Studies on Hemophilia: III. Some Physiological and Biochemical Properties of the Antihemophilic Principle of Normal Human Plasma, to be published.

It is hoped that antihemophilic plasma fractions will replace whole plasma in the control of this disease. At present they do not show uniform potency.¹⁹

That the coagulation defect in our subjects did not become worse under plasma therapy is of the utmost importance. We found no evidence of refractoriness. This is in contrast to the result in the patient of Munroe and Jones³ whose condition is reported to have become resistant to blood or plasma transfusion and whose blood was shown to contain an anticoagulant. Whether this development can be attributed to the use of frequent transfusions, as is claimed by the authors, or whether it appeared spontaneously, as is suggested in the case of Lawrence and Johnson,¹⁰ is still uncertain.

Persistence of the coagulation defect after the therapeutic period, while throwing no definite light on the pathogenesis of hemophilia, suggests a fixed inability of the hemophilic person to elaborate the antihemophilic moiety found in normal plasma.

Our finding of relative ineffectiveness of intramuscular administration is not in accord with other reports⁶ of accelerated coagulation following injections of plasma or plasma "globulin" substance via this route. The discrepancy is perhaps related to differences in the assay methods and the amounts of materials used.

Since the effect of 50 or 100 cc. of plasma administered intravenously may not be distinguishable from that of 10, and 650 to 750 cc. may not be distinguishable from 150 to 190 cc., great caution should be exercised in comparing the antihemophilic potency of different biologic materials on the basis of their clot-promoting action *in vivo*. The ability to superimpose curves representing the degree and duration of clot acceleration *in vivo* may be an unreliable basis for drawing conclusions with regard to antihemophilic potency.

The hemorrhages experienced by our subjects, most of them occurring when the clot-promoting effects of the last administered plasma had largely disappeared, also attest to the value of continued repeated plasma therapy, since the hemorrhagic phenomena, coinciding with lapses in therapy, serve as a control for the therapeutic approach. It is probable, also, that minor hemorrhagic phenomena, such as were observed in our subjects after definite trauma and as might be expected on the basis of clotting times rising intermittently, were prevented from becoming major episodes by the frequent administrations of plasma. On the other hand, persistent bleeding, even when the clotting time is maintained between ten and twenty-two minutes and in the absence of infection, suggests that factors other than delayed coagulation of blood may be involved in the hemorrhagic phenomena of hemophilia.

The therapeutic method which we have used is admittedly laborious and cumbersome. It requires an efficient blood bank with a positive balance of blood. The sizeable dose of plasma and its relative ineffectiveness when given intramuscularly exclude nonintravenous routes of administration. The person with hemophilia becomes, furthermore, "tied" to a hospital institution. Nevertheless, we believe that the prophylactic management of hemophilia by means of plasma is not only effective but also feasible. Most hospitals have blood banks. The whole procedure can be entrusted to a blood bank nurse. Patients can be

scheduled to appear three mornings a week in the outpatient department for their treatments. After five to ten minutes of infusion, the patient is free to leave.

The supply of veins has presented no great problem in the adult patient, although our subjects were repeatedly subjected to many additional venipunctures for experimental purposes. In some of the patients, furthermore, many veins had already been destroyed by previous blood transfusions and hemorrhages.

Against the benefits derived from plasma must be weighed possible ill effects such as reactions and the transmission of infectious diseases. Obviously, this danger would still exist when and if plasma fractions became therapeutically practical.

The incidence of reactions to plasma in our group was smaller than that reported by other observers,²⁰ although it should be pointed out that in our study each member of a small group received a large number of plasmas, whereas in other studies each recipient in a large group was given one, or perhaps several, plasma infusions. It is of interest that the incidence or severity of reactions was no greater toward the end than at the beginning of the study. We obtained no evidence that passive transfer of sensitivity to allergens from donor to recipient occurs.²⁰

The absence of reactions attributable to incompatibilities between donor plasma and recipient red cells is probably due both to the small volume of each infusion and to the relative rarity of extremely high agglutinin titers.²¹

The frequent administration of plasma for the control of hemophilia raises the important question of the likelihood of "serologic" jaundice by this procedure.²² The occurrence of jaundice in 1 patient is of interest in this regard, although we cannot be sure that this was an episode of serologic jaundice. If we assume that it was, our figures²³ suggest that the incidence of infectiousness in the population at large is approximately 1 in 540 if the 3 other persons with hemophilia are considered still susceptible to the disease; of 1 in 130²⁴ if they are excluded.²⁵

SUMMARY AND CONCLUSIONS

The intravenous infusion of freshly processed, frozen, normal human plasma three to four times weekly provides a therapeutic approach to the effective control of hemophilia. On this regimen the status of 4 persons with hemophilia has been strikingly improved. The clot-promoting effect of plasma was constant over a period of twelve to twenty months. The underlying coagulation defect remained unaltered. The duration of the effect of normal plasma is related, but not proportionately, to the size of the dose. Intramuscular administration of plasma is relatively ineffective. The incidence of reaction was 1.2 per cent. No reaction could be attributed to incompatibility of blood groups. One patient contracted what was considered to be mild serum jaundice.

PHEOCHROMOCYTOMAS

GEORGE F. CAHILL, M.D.
New York

Tumors of pheochrome tissue have been considered to be among the rarer tumors, but with increasing interest in all types of hypertension and with improvements in diagnostic methods, these tumors have been recognized more frequently than formerly. The syndrome of "paroxysmal hypertension" that has been considered typical of tumor of pheochrome cells is familiar to all, but with the finding of more of these tumors observers now realize that many of them produce symptoms of persistent unremitting hypertension resembling the so-called essential hypertension. It has also been shown that some tumors arising from pheochrome tissue, notably the carotid body, apparently do not cause the hypertensive symptoms.

SYMPTOMS AND MANIFESTATIONS

The usual symptom complex is either spontaneous or induced and consists of a pounding headache, a pronounced beating of the heart with epigastric distress and a constriction of the hands and feet, often associated with a sense of impending death, lasting a few minutes to several hours. It is usually followed by excessive perspiration, weakness and exhaustion and sometimes shock. Associated with the attack is a decided rise in both systolic and diastolic blood pressure and a subsequent fall to the usual normal or lower levels at the termination of the attack. In addition, blood and urine examinations at the time of the attack show sugar curves somewhat similar to those seen in diabetes mellitus. It has been recognized that the attack is due to the effect of the release of an excess of a pressor substance, epinephrine, from the increased number of pheochrome cells in the tumor. At times death may result from the excess epinephrine released.

Continuous Hypertension.—It has been pointed out by Palmer and Castleman,¹ Howard and Barker² and Quinby³ that a number of these cases do not present this typical intermittent syndrome but have a sustained continuous hypertension that when present has confused the observers so that for a long time the condition remains unrecognized. A number of times unsuspected tumors of the pheochrome tissues have been accidentally discovered during the operative procedure of sympathectomy for continuous hypertension. The recognition that such continuous hypertension may be the result of a more or less continuous release of excess epinephrine is well illustrated by the following cases.

CASE 1.—J. L., a girl aged 12, was admitted Sept. 2, 1943 with a complaint of excessive perspiration and loss of weight for two years. She was intolerant of heat and refused covers

even on cold winter nights. She complained of a fast beating heart and used only the slowest of movements because of her apprehension of her heart beating. She was excessively thin, with a moist skin, and showed a blood pressure of 210 systolic and 150 diastolic, which was lower when she was erect and higher when she was prone. Her basal metabolic rate was plus 50 to 65. From Sept. 2, 1943 to Aug. 16, 1944, she was studied in a number of admissions in which her various metabolic studies showed normal creatine-creatinine ratio and a reduced serum iodine (4.8 micrograms per hundred cubic centimeters; normal for her age, 6.2). The usual cold pressor tests showed immediate rise in blood pressure. Injection of 0.2 cc. epinephrine intravenously produced an immediate increase of her subjective complaints and increase in blood pressure. Her fundi showed a moderate degree of papilledema of disks with obliteration of disk margins bilaterally and increased congestion of the vessels. Auriculoventricular nicking was not

Chart 1 (case 1).—Systolic blood pressure taken at the time of first operation, showing the immediate drop in blood pressure on removal of the first tumor and the rapid rise to former levels due to the presence of the second tumor.

noted. There were at first no hemorrhages or exudate. Results of a glucose tolerance test were within normal range, and she had no elevation of blood sugar or sugar in her urine. She showed no appreciable change under therapy with strong iodine solution U. S. P. Her true condition was finally suspected, and with an air insufflation roentgenogram a small tumor of the left adrenal was visualized. This was removed through a left flank incision on Aug. 16, 1944. She had the pronounced variations of blood pressure seen in these cases at the time of operation with a severe drop on removal of the tumor, but in a few minutes the blood pressure ascended again to high levels. Another tumor was then suspected to be present, and anteriorly in the incision there was revealed a mass in front of the pancreas. Since in all preceding cases the blood fell to normal or lower than normal levels and remained there, this immediate rise in blood pressure was thought to be due only

2. Howard, J. E., and Barker, W. H.: *Bull. Johns Hopkins Hosp.* **61**: 371, 1937.

3. Quinby, W. C.: *Tr. Am. A. Genito-Urin. Surgeons.* **36**: 103, 1943.

to additional excess pheochrome tissue elsewhere. The adrenal tumor microscopically was a pheochromocytoma.

She made a good recovery from the first operation, but her symptoms persisted. During this convalescence it was suggested that an epinephrine antagonist (2-[1-piperidylmethyl]-1,4-benzodioxan) be used intravenously to determine whether

Chart 2 (case 1).—Effect of 10 mg. and 20 mg. of benzodioxane on the systolic pressure in the period before the second tumor was removed.

there was excess epinephrine in her blood. A significant fall in blood pressure was the result of the intravenous administration of the benzodioxan with a gradual rise to former levels. A number of injections were done, all with similar results. She was then again operated on and an extra-adrenal pheochromocytoma removed transperitoneally from the left preaortic area just superior to the pancreas. Immediately after the removal of the tumor her blood pressure declined to 110 systolic and 60 diastolic; it has remained around that level to date, with complete relief from all her former symptoms. She has gained weight back to normal for her age. Her metabolic changes returned to normal range and her retinal changes disappeared. The benzodioxan tests subsequent to removal of the tumor showed no alteration of the blood pressure.

This particular case was confusing because of the supposed rarity of these tumors in children and because a syndrome of continuous unremitting hypertension was presented. The presence of an intra-adrenal tumor was established by the air insufflation roentgenograms, and the failure of the blood pressure to remain low after removal of the first tumor made a second extra-adrenal tumor suspected. This was confirmed by the effect of the benzodioxan test, although, this being the first case in which the effects were registered, the value of the test had not been established.

Change to Sustained Hypertension.—The change in some of these cases from remittent to sustained hypertension is illustrated by the following cases.

CASE 2.—D. B., a girl aged 10, was admitted Feb. 20, 1946 with nervous attacks and excessive perspiration for three years. At first the attacks consisted of nervousness, shortness of breath, epigastric pain and nausea followed by profuse sweating, and they occurred about every two weeks. The attacks became more frequent, and at admission and during study she had no periods of remission. During hospital observation her blood

pressure varied from 210 systolic and 160 diastolic to 185 systolic and 130 diastolic. She showed no physical changes except overaction of the heart. She was studied for thirty days, in which she showed no sugar in her urine and normal glucose tolerance readings. Her fundi showed changes similar to those in case 1 and according to the examiner⁴ were seen in no other condition than that observed in the former case. A test with the benzodioxan similar to that done in case 1 showed a significant drop (50 mm. systolic plus) in blood pressure, which remained depressed for ten minutes. Repetition of the test produced similar results. Intravenous pyclograms showed normal nondisplaced kidneys, and air insufflation roentgenograms did not reveal an enlargement of either adrenal. A diagnosis of extra-adrenal pheochromocytoma was made. It was suspected to be in the upper part of the abdomen.

A transperitoneal operative exposure showed a retroperitoneal tumor at the bifurcation of the aorta (Zuckerkind's body) and another large tumor in the epigastric area, retroperitoneal and covered with large cirrroid, dilated veins. The anterior veins were doubly ligated and cut. When attempts were made to separate the vena cava from the large tumor, there was pronounced increase in pulse and pressure and the pulsation suddenly ceased. Attempts at resuscitation failed.

Chart 3 (case 1).—Systolic blood pressure taken during the second operation, showing the almost immediate drop to low level after removal of the second tumor. There was apparently no more excess epinephrine being secreted after removal of the tumor and the conclusion reached was that all secreting tumor tissue had been removed.

Injections of the benzodioxan given during the pronounced change in blood pressure had no effect.

An autopsy showed an extra-adrenal pheochromocytoma between the aorta and the vena cava, intimately attached to

4. Bruce, G. M.: Tr. Am. Ophth. Soc. 45:1, 1947.

both and the size of an orange. A second pheochromocytoma at the bifurcation of the aorta, about the size of a small plum, was also found. Both adrenals and kidneys were anatomically normal. The patient had hypertrophy of the heart, atheromatosis of the aorta and coronary vessels, cysts of the ovaries and mild adenomyosis of the uterus. Nephrosclerosis was not present, a fact brought out by Howard and Barker, who wrote that if it was present it was only so in a mild degree.

This child showed the vascular changes seen with continuous hypertension, except for the supposed specific changes in the fundi. The air insufflation roentgenograms showed anatomically normal adrenals, but the air did not infiltrate around the epigastric tumor because of the tight fascial planes over the tumor. Infiltration of air around an extra-adrenal tumor so that it is visualized has apparently only been rarely seen and only when the fascial spaces are not under pressure and are connected with the perirenal area. This has occurred only once in our department.

This, the second case in which a significant reduction occurred in the blood pressure with injections of the benzodioxan, gave more significance to the test, especially so since no changes occurred in patients with

Chart 4 (case 2).—Effects of 12 mg. of benzodioxane on the systolic blood pressure.

known essential hypertension; in a number of patients suspected to have pheochromocytoma results of the tests were negative, and on operative exploration no tumors were found. The determining factor of the diagnosis was the positive reaction to the benzodioxan

test with a history of a gradual change from paroxysmal hypertension symptoms to more or less continuous hypertension.

Retinal Changes.—The peculiar retinal changes in these 2 cases (separately reported by Bruce) Bruce stated that he had not seen before and definitely not

Chart 5 (case 2).—Systolic blood pressure recordings at operation, with extreme elevation on attempt to isolate and ligate the vessel to the vena cava and immediate fall to zero with the death of the patient.

in other cases of hypertension. The papilledema and disk margin blurrings with fluffy exudate and hemorrhage were next seen by him in a third case, and the patient was referred into the hospital with the diagnosis of suspected pheochromocytoma based on the eye examination alone, associated with hypertension.

CASE 3.—P. D., a boy aged 11, was admitted Oct. 4, 1946 complaining of failure of vision for one week. The objects in the room were blurred and he was unable to read. He was examined by an ophthalmologist on the day of admission; (1) hypermetropia, (2) exudate in the retina and (3) hypertension were found. He had excessive sweating and thirst associated with a pounding headache, abdominal pain and nausea and vomiting and a pounding heart beat for three years. These attacks occurred at intervals, precipitated by excitement or activity; they usually occurred every month or so, lasted a day, and were followed by diaphoresis, weakness and loss of appetite. Blood pressure readings in between the attacks were reported as normal.

He was a healthy-appearing boy, somewhat apprehensive. His blood pressure was 260 systolic and 190 diastolic. A severe pounding headache developed, with pallor, sweating, nausea and vomiting and with a pulse rate of 150 and blood pressure of 270 systolic and 210 diastolic. The attack lasted

two days with listlessness following. A test with the benzo-dioxan after the attack showed a drop of blood pressure to 138 systolic and 110 diastolic, lasting only a few minutes. His pressure slowly fell in three days to 118 systolic and 82 diastolic. Air insufflation roentgenograms showed the left adrenal and kidney normal in size and position. The right kidney was small and poorly delineated by the air, and there was no infiltration at the hilus. The left adrenal looked normal. Intravenous and retrograde pyelograms showed lessened secretion in the right kidney diagnosed as "hypoplastic." While under observation he improved clinically and his eye-ground changes regressed. At no time did he show sugar in his urine, increase in sugar in his blood or abnormal sugar tolerance reaction. By the twenty-third day his improvement was pronounced, with normal blood pressure; he was able to read and was up and about.

He was operated on Oct. 29, 1946 under tribromoethanol-nitrous-oxide-oxygen anesthesia, and a transverse incision was made. A tumor about the size of a peach mesial to the hilus of a hypoplastic right kidney was removed with the kidney. The right adrenal was normal. During the entire procedure the blood pressure remained relatively stable and exhibited no untoward rise or decline. His recovery was excellent, his blood pressure remaining around 120 systolic and 80 diastolic, and his retinal changes regressed. On the ninth day another trial of the benzo-dioxan was given (0.6 Gm.), with no significant

Chart 6 (case 3).—Effect of 12 mg. of benzo-dioxane on the systolic blood pressure.

rise or fall after the administration of the drug. The pathologic report was (1) pheochromocytoma of aberrant adrenal medullary tissue, (2) hypoplasia of the right kidney and (3) calcium deposits in the right kidney. The tumor showed pronounced degenerative changes throughout, due to infarction caused by thrombosis in the main artery to the tumor.

From these 3 cases, the following inferences may be drawn, if such inferences are permissible: The syndrome occurs in children more often than shown by the few cases reported. The continuous hypertension phenomena may be seen oftener in children, and

Chart 7 (case 3).—Systolic blood pressure recordings during operation. The patient had spontaneous infarction of vessels to the tumor, with amelioration of the symptoms previous to operation, and as a result there was little change during operation and following removal of the tumor.

when they occur they may be associated with characteristic retinal changes. In children changes in metabolism occur but changes in blood sugar and urine resembling diabetes are not so frequent (at least they did not occur in any of these 3). In children multiple tumors may occur; on removal of one tumor the failure of the blood pressure to stay within low records should make an additional tumor suspected. In these 3 children five tumors occurred; only one of these was intra-adrenal; the other four were extra-adrenal. A spontaneous infarction occurring in 1 patient relieved all symptoms, so that operative removal was without incident.

The usual tumor is seen more frequently in adult life, occurs more often in the female (our cases: 10 females and 4 males). They are usually benign (McKeith⁵ indicated that 9 per cent were malignant), and according to McKeith⁵ they are 9.7 per cent bilateral.

The tumors are mostly seen intra-abdominally. In 1 case the tumor was reported to be intracranial.⁶ In 3 cases tumors have been reported as intrathoracic; one tumor was successfully removed by Mayer.⁷ Multiple tumors occurred in our cases 3 times in 14. The patient whose thoracic tumor was successfully removed

7. Mayer, H.: Personal communication to the author.

by Mayer still has some symptoms of excess epinephrine, but my co-workers and I were able to demonstrate normal adrenal shadows by air insufflation roentgenograms.

BASES FOR DIAGNOSIS

A diagnosis of pheochromocytoma depends on (1) a typical attack and associated clinical findings, among which may be characteristic retinal changes in children; (2) evidence in a case of so-called essential hypertension of symptomatic and clinical findings characteristic of the pheochromocytoma syndrome; (3) demonstration in the blood of a pressor substance as

B.P.
Syst.

Chart 8 (case 4).—An adult with a large tumor and paroxysmal type of hypertension. Effects of 20 mg. of benzodioxane on the systolic blood pressure.

shown by Beer, King and Prinzmetal⁸ or a significant reduction in the blood pressure associated with the intravenous injection of an epinephrine antagonist as the benzodioxane series; (4) precipitation of an attack in a resting stage by an epinephrine-producing stimulus as described by Roth and Kvale⁹; (5) roentgenographic evidence of the presence of a tumor, either without or with perirenal air insufflation or by renal displacement with pyelographic mediums.

The use of the various steps in the diagnosis are illustrated by the following typical case.

CASE 4.—K. G., a woman aged 42, was admitted on Feb. 7, 1947 with hypertension and hyperthyroidism of one year's

standing. She had attacks of headache, heart pounding, epigastric distress and pronounced sweating. These attacks were associated with hypertension (220 systolic and 130 diastolic) and glycosuria. The eyegrounds showed slight sclerosis of the retinal vessels with a slight haziness of the temporal margin of the left disk. These were seen by the same ophthalmologist who had seen the retinas of the children and were not characteristic of pheochromocytoma. Her basal metabolic rate was +23 per cent. The fasting blood sugar was 153 mg. per hundred cubic centimeters and nonprotein nitrogen 24 mg. Phenolsulfonphthalein excretion was 80 per cent in two hours. The serum sodium was 140.7 mg. The benzodioxane test showed a fall of blood pressure to 135 systolic and 80 diastolic, with a rise gradually in fifteen minutes to the level before injection. The intravenous pyelograms showed a normal pair of kidneys with increased motility. The air insufflation roentgenograms showed an ovoid tumor above the right kidney in the area of the right adrenal.

Through a transverse epigastric incision a pear-shaped tumor of the right adrenal was removed transperitoneally. There was the pronounced elevation of the blood pressure on ligation of the blood supply without handling of the tumor, as usually seen, and a rapid fall following removal. Epinephrine slowly administered intravenously gradually raised the systolic blood pressure from 60 to 100 in eight hours. Since removal of the tumor, after an uneventful recovery, her blood pressure remained on the average of 120 systolic and 80 diastolic for two months. At that time her basal metabolic rate was -5 per cent and she occasionally had a small amount of sugar in her urine.

The history characteristic of the classic syndrome with the establishment of presence of excess epinephrine by the antagonist and the delineation of the tumor by air insufflation roentgenograms made the diagnosis certain. The immediate fall of blood pressure and the gradual return to normal are characteristic of the removal of the usual solitary tumor.

A number of metabolic changes have been found with the syndrome. Hypermetabolism is of frequent occurrence and a differential diagnosis between hyperthyroidism and pheochromocytoma is sometimes difficult. In 1 of our children the lessened blood iodine level and poor response to administration of potassium iodide made the diagnosis of hyperthyroidism not tenable.

Elevation of serum potassium and increased urea clearance have been found. Increased peripheral blood flow is present. Reduction of cutaneous temperature occurs with the increased peripheral resistance. Profuse sweating which occurs with the ending of the attack dissipates the excess heat due to increased heat production and prevents a rise in temperature.

The glycosuria present may confuse the diagnosis and be resistant to the ordinary treatment of diabetes mellitus, and removal of the tumor may relieve both the hypertension and the glycosuria, as reported in the case by Duncan, Semans and Howard.¹⁰ This patient was older than the usual patient. We have noticed that the sugar changes occurred as the patients were older. In the 3 children reported on in this paper, the usual changes in blood sugar and urine were not associated with the syndrome. One patient (our

case 4) had glycosuria after removal of the tumor with abatement of all other symptoms.

Hysteria and psychoneurosis may present difficulties in determining whether a pheochromocytoma is present, as has been pointed out by Van Epps¹¹ and myself. In spite of failure to find positive evidence of excessive epinephrine by the benzodioxan test and although the adrenal glands appeared normal in air insufflation roentgenograms, when there were a suggestive history and simulated attacks exploration was done in a number of these cases in the hope of finding an extra-adrenal pheochromocytoma. The failure to observe a tumor gave us increased confidence in the benzodioxan test.

Chart 9 (case 4).—The systolic blood pressure recordings during operation. There was a rise in blood pressure on ligation of the tumor vessels and a pronounced fall to low levels after removal. This is the more frequent recording seen and occurs with solitary tumors.

The use of benzodioxan derivatives as indicators of excess epinephrine was first suggested by Goldenburg, Snyder and Aranow.¹² A simple method for this determination was sought because the use of a modified Pissenski method as reported by Beer, King and Prinzmetal⁸ was difficult and cumbersome and the apparatus and material available only in certain laboratories. A simple intravenous injection of a benzodioxan derivative with blood pressure studies was introduced by Goldenburg, Snyder and Aranow¹² in our case 1, with apparent confirmation of the finding of excess epinephrine and of the diagnosis. Since then they have shown that the blood pressure level in patients with "essential hypertension" is not influenced by the injection of the drug and that all other simulating syndromes

showed no changes in blood pressure. They also showed that in the 4 proved cases of syndromes due to pheochromocytomas the fall in blood pressure following the injection of the drug was significant and of diagnostic importance and that it apparently occurs only with excess secretion of epinephrine, and that in the 3 surviving patients no changes occurred in the blood pressure postoperatively after injection of the drug.

The histamine test was described by Roth and Kvale,⁹ who observed that intravenous injection of 0.05 mg. of histamine could immediately precipitate a hypertension crisis in a patient with pheochromocytoma. This we have not experimented with, because the recent positive cases were too serious to risk and that the diagnosis was established otherwise. We have, however, used the histamine test in those cases in which the reaction to the benzodioxan test was negative in order to have a double check, and in not any of such cases was the histamine test positive in result.

The use of air insufflation roentgenograms has been a safe and reliable indicator when the tumor is of the adrenal gland, and it is most satisfactory with small adrenal tumors that can be localized by no other method. Attempts made to delineate extra-adrenal tumors by fascial insufflation have not been very successful, having shown only one at the bifurcation of the aorta. The sealing of the fascial planes around the other tumors prevented the air from disseminating and outlining them.

TECHNIC

There has been a lowering of the mortality rate in surgical therapy of these tumors. The use of tribromoethanol in anesthesia induction has avoided precipitation of an attack. Epinephrine and adrenal cortical hormone should be available at operation and used if needed both during operation and afterward. One patient of ours with Cushing's syndrome and pheochromocytoma required cortical hormone subsequent to operative removal because of acute cortical adrenal deficiency after operation. Blood pressure readings are necessary almost continuously during operation. With multiple tumors the transperitoneal route has been more frequently used by us, although a high lumbar approach may be satisfactory for adrenal tumor. The handling of the tumor has been dangerous and should be reserved until all the vessels surrounding and connected with the tumor are ligated. The situations of some tumors make handling of the blood supply difficult and in some, such as our case 2, in a child with a large tumor between the vena cava and the aorta, temporary occlusion of the vena cava above and below the tumor may be necessary to prevent the escape of a lethal dose of epinephrine into the circulation. The use of the benzodioxan in that case in the small amount employed was without avail, probably because of the large amount of epinephrine released.

Following removal of a secreting tumor the immediate fall in blood pressure may be alarming. Intravenous administration of epinephrine has satisfactorily controlled this drop. A return to normal has been the

11. Van Epps, E. F.; Hyndman, O. R., and Greene, J. A.: Clinical Manifestations of Paroxysmal Hypertension Associated with Pheochromocytoma of Adrenal, *Arch. Int. Med.* 65:1123 (June) 1940.

12. Goldenburg, C.; Snyder, H., and Aranow, H., Jr.: *J. A. M. A.* 135:971 (Dec. 13) 1947.

usual result when all the excess epinephrine tissue has been removed. A rapid elevation of the systolic blood pressure in ten minutes or less following removal of the tumor and the elevation to near its former levels in our experience is an indication that a second tumor is present.

The postoperative care has been the one of combating an apparently depleted epinephrine state with accompanying low blood pressure. This has been successful with intravenous infusions with epinephrine. Studies of sodium and potassium balance showed only in 1 case a change suggestive of cortical depletion and that was in a case with associated mild Cushing's disease.

Most of these tumors are benign and unilateral; MacKeith's review, as stated before, indicated that 9 per cent were malignant and 9.7 bilateral. In 9 of his reviewed 165 cases there was an associated cutaneous neurofibromatosis, and these tumors were all bilateral.

In 2 of our 14 cases there were presumed to be metastases and the tumors were considered to be malignant. Attempts made by Masina¹³ to grow our recent tumors in the anterior chamber of the eye of rodents has been unsuccessful. All tumors seen by us were of chromofin and ganglion cells. They contained abnormal amounts of epinephrine by assay, and the abnormal amounts were demonstrated as present in the tissue by staining methods.

SUMMARY

Pheochromocytomas occur mostly in the adrenal but do occur in other pheochrome tissue. The syndromes are due to excess epinephrine released into the blood. They may give typical syndromes of paroxysmal hypertension or may resemble essential hypertension. They may occur at any age, and the tumors may be multiple. The steps in the diagnosis are illustrated, and the diagnosis is often certain.

ABSTRACT OF DISCUSSION

DR. EARL E. EWERT, Boston: That Dr. Cahill and his group should receive the gold medal for their classic work is no surprise. His experience with adrenal tumors extending over some twenty-five years has generated in all the appreciation that this one sort of rarity is more common clinically than has been suspected. The food for thought that he has offered is that persistent hypertension may be present in adrenal tumors and this more commonly in children; that a normal glucose tolerance range may be present and that sugar is absent from the urine and there is no elevation of the blood sugar; that adrenal chromaffin tumors may be multiple and extrarenal; that removal of a single chromaffin tumor without relief indicates the presence of an extrarenal tumor. Other observations that my associates and I have made in a small series are: In every patient with peculiar vasomotor paroxysms the possibility of a pheochromocytoma must be investigated. All hypertensive patients undergoing sympathectomy should have besides their normal routine urograms some of the specific diagnostic tests. Also, patients with typical epileptiform seizures should be considered as possibly having chromaffin tumors. A "mecholyol bromide" test is added to those that have already been given and to the new test that Dr. Cahill mentioned, the dioxan test. The "mecholyol" test consists of administering 25 mg. of the drug subcutaneously after a period of rest to obtain a stabilized blood pressure and pulse rate. The blood pressure and pulse rate are then recorded after "mecholyol" is given at one minute intervals, until they return to normal, in fifteen or twenty or thirty minutes. A positive reaction is shown by a decided rise in systolic and diastolic pressures. In the case tried, there was

a rise of 106 mm. of systolic blood pressure and 60 mm. of diastolic blood pressure above the resting level following a preliminary fall lasting about one minute. The pressure returned to normal in fifteen minutes. Associated with the rise in blood pressure were all the symptoms characteristic of a paroxysmal attack of hypertension due to a chromaffin tumor. In addition, the patient experienced the side reactions of "mecholyol," which include nausea, asphyxia livida, sweating and dyspnea, which may be controlled by the administration of atropine. The controls were tried in 27 additional patients, ages 20 to 60; 7 were normal and 20 had hypertensive vascular disease. In the 27 controls, the reaction was positive in all, and of the 22 patients in whom the cold pressor test was performed, 17 showed a normal response and 5 showed a rise of more than 20 mm. and may be considered as hyperreactors. Of the 9 patients in this group on whom histamine was tried, 5 had a rise in blood pressure of 20 mm. or more and are considered as hyperreactors. During operation the sharp drop in diastolic pressure is the point at which the patient may be lost. This is the crucial point. The operation for pheochromocytoma is delicate; the internist and the anesthetist must be conscious of the catastrophe which may occur suddenly in manipulation of the tumor, even when ligation of the vessels has been taken care of before removal of the tumor and when one thinks that he has been especially careful not to manipulate the tumor and discharge amounts of pressor substance into the blood stream.

DR. SEYMOUR F. WILHELM, New York: About fifteen years ago, Dr. Cahill discovered that the injection of air or gas into the perirenal space was of great aid in visualizing the larger adrenal tumors. However, in the delineation of the normal adrenal gland, the lesser enlargements, and the smaller tumors, my associates and I have found the simple roentgenogram following perirenal insufflation disappointing. We have been unable definitely to make up our minds as to the size of the adrenal gland or the absence or presence of any enlargement. We looked for other methods and tried laminography, by means of which a definite section of the body can be localized and the tissues above and below eliminated or blurred. By this means, we have been able to get rather sharp pictures of the normal adrenal and also of the lesser enlargements. I would like to ask how much adrenal gland tissue can be resected from the human being without causing Addison's disease. I have a female pseudohermaphrodite who had hyperplasia of both adrenals from whom I successfully resected the entire left adrenal gland, weighing 21 Gm., and about half the other adrenal. I would appreciate Dr. Cahill's telling us something about his experiences.

DR. GEORGE F. CAHILL, New York: I want to congratulate Dr. Wilhelm for going on with his laminographic work, which is really good. He has developed the simple thing that we had started with and carried on and has really advanced the outlining and the interpretation of these films definitely. As far as the amount of adrenal tissues to remove, that is difficult. One can take out one adrenal completely, but when one resects an adrenal, it is difficult to handle the hemorrhage. For the part of the adrenal left one does not know how much blood supply has been disturbed; there may be thrombosis; all the adrenal tissues may be killed. Of course, there are accessory adrenals known as Marchand bodies, occurring anywhere from the adrenal to the gonad. Tumors have occurred of these, not of the adrenal itself, with cortical syndromes characteristic entirely of the adrenal cortical syndrome. However, one cannot be sure that a particular patient will have some more Marchand bodies. I do not know yet how much adrenal to take out. I err on the side of leaving some in. The pheochromocytoma is extraordinary. The whole thing is dramatic. It is the only hypertension that one cures the cause of. One can now definitely cure it with apparent safety with the exception of that ten minutes of handling the tumor. Once the surgeon gets past that point, usually he is all right. The patient goes on; some patients have cortical deficiency following the handling of the tumor, but the deficiency can be corrected. We had 1 patient that had both a Cushing syndrome and a pheochromocytoma in the same adrenal, so that the deficiency subsequent to the operation was cortical deficiency and we had to treat it like an addisonian crisis.

TREATMENT OF ADVANCED MAMMARY
CANCER WITH TESTOSTERONEMAX CUTLER, M.D.
and
MELVIN SCHLEMENSON, M.D.
Chicago

The purpose of this paper is to present the results in 20 consecutive cases of advanced mammary cancer in which testosterone propionate was used. The minimum observation period is one year.

Ulrich¹ (1939) was the first to describe testosterone therapy in advanced mammary cancer. Although the doses were too small to produce chemical castration, his 2 cases showed a favorable response. Loeser,² in the same year, reported 2 patients, who had recurrent mammary cancer, treated with testosterone for menorrhagia. They lived for eighteen months without further recurrence. It was not stated whether or not recurrence was present at the beginning of testosterone therapy. Prudente³ used testosterone prophylactically following mastectomy in doses adequate to produce ovarian suppression.

So far as we can determine, 92 cases of advanced mammary cancer treated with testosterone have been recorded in the literature; in addition, Prudente³ has studied the prophylactic effect in 63 cases and Snapper⁴ has treated 29 patients prophylactically with combined castration (surgical or with roentgen rays) and testosterone. In January 1948, Adair⁵ wrote that 450 patients had been treated and observed by his group; 233 treated for advanced cancer and 217 treated prophylactically following radical mastectomy. Of the group with advanced cancer, 28 cases of advanced cancer have been reported in the literature up to the present writing.

Isolated favorable results in advanced cases have been reported.⁶ These include cases of both soft tissue lesions and skeletal metastases. In Snapper's⁴ 29 cases, castration (either surgical or with roentgen rays) combined with testosterone therapy did not protect against the subsequent development of distant metastases in cases with axillary involvement at the time of operation. Prudente³ reported that in his 63 patients treated with radical surgical intervention and testosterone, the

instances of three, four and five year survivals were increased by approximately 100 per cent as compared with a series treated with surgical intervention alone.

TESTOSTERONE

The property of testosterone for increasing the retention of sodium and potassium has been well established (Thorn and Engel,⁷ Kenyon and his co-workers⁸). In addition, Kenyon and his co-workers⁸ and Abels, Young and Taylor⁹ have demonstrated increased protein nitrogen retention. Kenyon and his colleagues⁸ treated 4 eunuchoid persons with testosterone propionate and observed a gain in weight due largely to water held in association with the sodium and nitrogen. Butler, Talbot and MacLachlan¹⁰ concluded from their studies that potassium was retained primarily in the tissue fluids. The electrolytes and nitrogen retain water; consequently a gain in weight occurs. The increased weight is lost rapidly following cessation of treatment. Thorn and Engel⁷ noted that decided diuresis and loss of weight occurred seventy-two hours after testosterone therapy was stopped. In addition, there was increased excretion of sodium, chlorides, potassium, inorganic phosphorus and total nitrogen. Thus, the evidence indicates that the electrolytic effect, in association with the protein nitrogen retention, is responsible for a transient rather than a permanent gain in body weight. For these reasons, a gain in weight *per se* does not necessarily indicate a favorable influence on the disease. This effect was observed clinically in several patients in whom peripheral edema developed while they were receiving testosterone. It is for this reason that testosterone must be used cautiously in patients with cardiac disease.

The changes in blood calcium and blood phosphorus during testosterone therapy are not well understood, and there is a decided divergence of opinion in the literature. Adair⁵ has described decided reduction in the serum calcium level in patients with metastasis to bone and has interpreted this decrease as evidence of calcium deposition in bone or a cessation of osteolysis. In none of his reported cases which responded favorably was there a change in the serum calcium which could be interpreted as significant. Snapper⁴ reported 29 patients treated with castration and testosterone and noted no significant change in the serum and phosphorus. Farrar and Woodard⁶ treated 33 patients with smaller doses of testosterone and reported an increase in serum calcium in some cases. Adair and Herrman¹¹ have noted that in patients with decidedly elevated serum calcium the condition of the patient is aggravated by testosterone therapy, and they have intimated that the drug should not be used under those conditions. While this, in general, is true, we have recently seen a patient with an elevated level of serum calcium who showed no untoward effects following administration of large doses of testosterone propionate. The level of the blood phosphorus has not proved to be of value in the evaluation of testosterone therapy.

Alkaline phosphatase is present where there is osteoblastic activity. This osteoblastic activity may be either reparative following osteolytic metastases or it may

represent osteoblastic metastases, or, and most important, it may represent a combination of both processes existing simultaneously. Thus a rise in the level of alkaline phosphatase may mean more osteoblastic metastases rather than repair of osteolytic lesions. Adair and Herrman¹⁰ have reported one case with favorable response in which there was a rise in the level of alkaline phosphatase accompanying the calcification of the skeletal metastases. It must be borne in mind, however, that the level of the serum alkaline phosphatase is dependent on the degree of osteoblastic activity. Since it is well established that metastasis to bone without treatment may cause a rise in the level of serum alkaline phosphatase, it is our belief that this index is not a safe criterion of response to treatment.

Subjective changes which occur in patients receiving testosterone are well known. These include hoarseness, facial hirsutism and other signs of virilism; in addition, there is usually a decided increase in libido. This latter effect has been well described by Abel.¹¹ Enlargement of the clitoris and development of an acneiform eruption on the trunk also occur and are usually very disturbing. Geist and his co-workers¹² have demonstrated that as a rule more than 200 mg. of testosterone propionate per month is required to produce masculinization and cessation of menses. These effects are lost slowly after treatment is discontinued. A sense of well-being and some relief of discomfort is common, but this effect is usually transient. In our cases, once the favorable systemic effect of testosterone was lost, another course of testosterone did not renew the initial effect; however, Herrman, Adair and Woodard¹³ have reported cases in which the response to a second course of testosterone duplicated the favorable response of the first.

REPORT OF CASES

Twenty consecutive patients were treated; 19 had carcinoma and 1 had lymphosarcoma. Twelve showed no significant improvement; 11 of these died within one year after the beginning of treatment, and 1 died after fourteen months. Six of the 12 patients had only soft tissue involvement; the other 6 had only skeletal metastases. It is interesting that 3 patients experienced skeletal metastases while under treatment. We have no evidence that the disease was accelerated in any of the 12 cases which did not respond. There were no unusual reactions to the treatment.

Four cases showed transient improvement. In 1, multiple cutaneous nodules on the thoracic wall showed decided regression; however, the systemic disease became progressively worse, and the patient died from cancer. In a second case, a fixed ulcerated mass in one breast became more movable, but the ulceration increased. There was a temporary gain in weight and a decided improvement in her general condition; the effect, however, was transient. The disease became more progressive, and cancer developed in the opposite breast. In a third case, with pleural involvement and a severe cough, a sense of well-being was established and the cough diminished. Shortly after testosterone therapy was omitted, the condition became worse and the disease progressed. The history of the fourth case is presented in detail.

CASE 1.—C. C., a woman aged 66 years, was admitted in April 1944, complaining of a mass in the right breast. Examination disclosed the classic clinical signs of cancer. There

was no evidence of metastasis. Because of the patient's general condition, the operation (April 12) was limited to a simple mastectomy. Microscopically, the lesion was carcinoma. The intramammary lymph nodes were involved. Roentgen therapy was given to the axilla. There was no evidence of disease until May 12, 1945, when a small lymph node developed in the right axilla. July 30, 1946, the node measured about 3 by 3 cm. Roentgenograms of the chest, lumbar part of the spine and pelvis showed no metastasis. The chemical content (calcium, phosphorus and alkaline phosphatase) and structure of the blood and the urine were normal. On June 30, 300 mg. of testosterone propionate ("oreton") was injected intramuscularly and 150 mg. twice weekly until a total of 3,750 mg. had been given. After six weeks the node was slightly smaller, and at the end of eleven weeks it was barely palpable. The patient gained 6 pounds (about 3 Kg.) and felt well. The usual signs of masculinization were present. On October 18, intramuscular administration of testosterone was omitted and oral administration of 30 mg. of testosterone daily was begun. After two weeks the dose was reduced to 10 mg. daily. Examination remained the same until July 3, 1947, when a node of 2 cm. was again palpable in the axilla. The amount of testosterone given orally was increased to 20 mg. daily. The node became progressively larger, and on September 11 a right axillary dissection was performed. No evidence of carcinoma was seen in the specimen. There was no evidence of disease at the last examination, on April 29, 1948.

Comment.—There was no question in our minds that, clinically the node palpated in the axilla before the start of testosterone therapy was characteristic of metastatic carcinoma. Unfortunately, no tissue was removed for microscopic examination, and it is possible that our impression was not correct. Therefore, in this case we cannot make any statement concerning the effects of testosterone therapy. However, we have another case, not included in this report, which is almost identical with the one previously described except that methyl testosterone was used and, when the axillary dissection was performed, the specimen did show carcinoma. That patient subsequently showed evidence of widespread metastases.

These 4 cases represent the borderline group in which it is difficult to evaluate the effects of the medication. The possibility that the temporary response was coincidental cannot be excluded. It is more likely, however, that testosterone did play some role in the regression of the disease. In each of these 4 cases the disease at the time of treatment was confined to soft tissue.

Four cases showed definite improvement: 1 with skeletal metastases, 1 with skeletal and soft tissue metastases and 2 with soft tissue involvement. The case histories follow.

CASE 2.—J. C., a woman aged 42 years, was admitted on June 1, 1942, with a mass in the axillary portion of the left breast. Observations in roentgenograms of the chest were normal. On July 3 radical mastectomy was performed. The microscopic diagnosis was carcinoma. The axillary glands were not involved. There was no evidence of disease until April 26, 1946, when roentgenograms of the chest showed increased hilar adenopathy. Symptoms did not appear until October 25, when the patient began to complain of dyspnea and pain in the chest, pelvis and left leg. Roentgenograms of the chest showed pleural effusion on the right side. Examination of the thoracentesis fluid disclosed carcinoma cells. There was definite nodularity in the left supraclavicular space. Roentgenograms showed a large osteolytic lesion in the left iliac crest (fig. 1A) and a small lesion in the right femur. The chemical content (calcium, phosphorus and alkaline phosphatase) and structure of the blood and the urine were normal. On October 25, 30 mg. of testosterone propionate ("oreton") was injected intramuscularly, and 150 mg. was given twice weekly

11. Abel, S.: Androgenic Therapy in Malignant Disease of the Female Genitalia, *Am. J. Obst. & Gynec.* 49: 327, 1945.

12. Geist, S. H.; Salmon, V. J.; Gaines, J. A., and Walter, R. S.: The Biologic Effects of Androgen (Testosterone Propionate) in Women, *J. A. M. A.* 114: 1539 (April 20) 1940.

until a total dose of 4,050 mg. had been given. The dyspnea disappeared after two weeks. The fluid in the chest was almost completely absent according to roentgenologic studies on Jan. 1, 1947. On April 22 the osteolytic areas showed decided calcification and trabeculation (fig. 1B). Except for the facial hirsutism, the patient was comfortable. Intramuscular admini-

Fig. 1 (case 2).—A, before treatment. B, after treatment.

istration of testosterone was discontinued on January 20 and oral administration of 30 mg. of testosterone daily was begun. The masculinization was maintained, and, after 900 mg. had been taken orally, the dose was reduced to 10 mg. daily on September 27. At that time the patient complained of headache and diffuse pain in the chest. Her condition became progressively worse; on November 3, dyspnea increased, she was losing weight and her general condition was deteriorating. Skeletal metastases became more widespread. Sixteen hundred cubic centimeters of fluid was aspirated from the chest. On November 3, 300 mg. of testosterone propionate ("oreton") was injected intramuscularly, and 150 mg. was injected twice weekly. This was continued for six weeks, but the patient's condition became progressively worse and she died on December 20.

Comment.—This case illustrates that soft tissue and skeletal metastases may be affected favorably in the same patient. It is also noteworthy that a second course of testosterone had no effect on the progress of the disease. The testosterone therapy suppressed menstruation permanently. There were no menopausal symptoms. The improvement lasted for eleven months.

CASE 3.—J. O., a woman aged 58 years, was admitted on Sept. 17, 1946. She complained of a lesion on the scalp of five months' duration. A report of biopsy was "suggestive of malignant growth." There was a raised red scaly lesion, 5 by 5 cm., on the left side of the scalp (fig. 2A). There was no hair in this area. The lesion was believed to be metastatic. With great hesitancy, the patient finally admitted that she had known of a lump in the left breast for several years and consented to an examination. In the left breast there was a large ulcerated lesion, with induration of the entire breast, and multiple cutaneous nodules extending into the left

axilla. The right axilla contained a firm node 2 by 2 cm. Multiple small subcutaneous nodules extended onto the abdomen. In addition, there was a hard mass, suggestive of intra-peritoneal metastases, in the right lower abdominal quadrant. Roentgenograms of the chest and lumbar part of the spine showed no evidence of metastasis. Biopsies from the scalp and thoracic wall showed carcinoma. Sept. 19, 1946 the blood chemistry and morphology as well as the urine were normal. On September 18, 300 mg. of testosterone propionate ("oreton") was injected intramuscularly and 150 mg. twice weekly, until 4,650 mg. had been given. During the first two weeks the patient complained of abdominal cramps and nausea. There was a decided response. The scalp lesion healed, and hair grew in the area (fig. 2B). The lesion of the breast regressed, and many of the metastatic nodules resolved. The patient gained 13 pounds (about 6 Kg.). There was no significant change in the chemical content of the blood. On December 30, intramuscular administration of testosterone was discontinued and oral administration of 30 mg. of testosterone daily was begun. The masculinization persisted, and the patient felt well. All the lesions continued to regress. On Feb. 21, 1947, the amount of orally administered testosterone was reduced to 20 mg. daily. Masculinization was still present. On March 4 the patient began to complain of pain in the back. Roentgenograms showed metastases to the skull, lumbar vertebrae and lungs. Testosterone therapy was discontinued, and 7.5 mg. of diethylstilbestrol monomethyl ether ("monomesterol") daily was given. The pain in the back did not improve; treatment with diethylstilbestrol monomethyl ether was stopped, and on May 12 roentgen rays were given to the lumbar part of the spine, with complete relief of pain. The patient continued to feel well for approximately five to six months, despite multiple meta-

Fig. 2 (case 3).—A, before treatment. B, after treatment.

stases; however, her condition became progressively worse, and metastases to the liver and other organs developed. She died on June 7, 1948, twenty-one months after the beginning of hormone therapy.

Comment.—The healing of the scalp metastases and regression of the cutaneous nodules represent definite evidence of the effect of testosterone on the soft tissue metastases. Interesting microscopic changes in the

composition of the tumor in a series of biopsies were seen. Skeletal metastases developed in this patient while she was receiving masculinizing doses of testosterone. The use of large doses of estrogenic substances did not alter the course of the disease.

CASE 4.—C. V., a woman aged 43 years, was admitted June 3, 1947. In August 1944 a left radical mastectomy was performed for cancer followed by postoperative radiation. The patient was well until March 1947, when she began to complain of pain in the pelvis. Roentgenograms showed complete destruction of the inferior ramus of the left pubis and ischium; there were also destructive lesions in the right femur and right humerus (fig. 3A). Between March 15 and April 16, small doses of roentgen rays had been given to the pelvis, lumbar part of the spine and right shoulder at another hospital, without relief. There was no external evidence of disease except a slight limp. On June 17 she received 300 mg. of testosterone propionate ("oreton") intramuscularly and 150 mg. twice weekly thereafter, up to a total dose of 3,850 mg. This was followed by oral administration of a maintenance dose of 60 mg. of testosterone daily. After two months, the bone lesions began to calcify and there was complete absence of pain (fig. 3B). This palliation continued until April 1948, when again the patient complained of pain in the shoulder and pelvis. Roentgenograms showed increase in the osteolytic metastases. Another course of testosterone was begun, but the disease continued to progress.

Fig. 3 (case 4).—A, before treatment. B, after treatment.

Comment.—The effects of the roentgen therapy and testosterone therapy cannot be entirely separated in this case; however, the fact that the patient did not receive any appreciable relief from the roentgen therapy, but did show decided improvement after the testosterone therapy was begun, makes it reasonable to assume that the effect was due primarily to the testosterone.

CASE 5.—N. T., an obese diabetic Negro woman aged 62 years was admitted Dec. 10, 1946, complaining of a mass in the right breast of two years' duration. Examination disclosed a hard fixed mass, 10 by 7 cm., in the upper outer quadrant of the right breast. There was definite cutaneous adherence and linear induration extending into the axilla. The size of the mass and its position prevented the arm from coming against the thoracic wall. Roentgenograms of the chest, lumbar part of the spine and pelvis did not reveal metastasis. Decided cardiac enlargement was evident. A clinical diagnosis of cancer was made, and a radical mastectomy advised. The patient categorically refused major surgical procedures. A biopsy showed carcinoma. On December 17, 300 mg. of testosterone propionate ("oreton") was injected intramuscularly and 150 mg. twice weekly, until 2,250 mg. had been given. On Jan. 2, 1947, after administration of only 900 mg. of testosterone, there was definite regression of the breast tumor and the patient stated that she was again able to put her arm by her side. At this time she complained of weakness, and there was increased swelling of the ankles. These symptoms were attributed to increasing cardiac decompensation resulting from water retention; however, testosterone therapy was continued. On February

15 the mass showed further regression and the linear extension into the axilla was no longer palpable. Because of the cardiac problem, testosterone therapy was discontinued and the residual mass was treated with radiation. Telecurietherapy was administered to the residual tumor between February 17 and March 23. The tumor continued to regress, and by December 29 it had disappeared; there was, however, a firm lymph node in the right axilla. The patient did not return again until Feb. 24, 1948, at which time the tumor had recurred, forming a mass 7 by 7 cm., with a cutaneous nodule 0.5 cm. in diameter. Biopsy of this nodule showed metastatic carcinoma. A roentgenogram of the chest at this time did not reveal metastasis.

Comment.—The caution which must be exercised in treating patients with cardiac disease is illustrated in this case. The effect of testosterone on the breast tumor and the subsequent further regression with telecurietherapy constitute a good example of the response of soft tissue metastases to these agents.

COMMENT

The favorable effects of testosterone on the course of the disease in some cases of advanced mammary cancer are reported; the response, however, is unpredictable and transient. Adair⁶ reported 3 patients, in whom the disease was confined to bone, living without evidence of disease for eighteen to twenty-four months after treatment. In our 4 cases in which definite improvement was shown, recurrence developed within one year. The longest period of improvement was eleven months. From the available evidence it seems advisable to withhold testosterone therapy in advanced mammary cancer until other well established procedures have reached the limits of their usefulness. It is for this reason that we have not used testosterone prophylactically as practiced by Prudente³ and more recently by Adair⁶ and Snapper.⁴ Because several patients who obtained palliation from testosterone suffered a recurrence of the disease after treatment was stopped, it is suggested that treatment should continue until the palliative effect is no longer evident.

It must be remembered that surgical castration and roentgen sterilization frequently produce results which are comparable to those seen with testosterone therapy and these procedures should not be abandoned. It is true that the availability of a constitutional agent such as testosterone is a great comfort to both patient and physician; however, final evaluation is not possible until further and more prolonged studies have been conducted. At present, the Therapeutic Trials Committee of the Council on Pharmacy and Chemistry of the American Medical Association is conducting an extensive and coordinated study of testosterone therapy in advanced mammary cancer, which is being pursued by various groups throughout the country. It is hoped that this study will produce a significant number of cases, with treatment under controlled conditions, to permit more definite conclusions.

SUMMARY AND CONCLUSIONS

Twenty patients with advanced mammary cancer were treated with testosterone propionate ("oreton"). Twelve showed no significant improvement, and 11 of these died within one year after the beginning of the treatment. One patient with lymphosarcoma of the breast was not improved. Four patients showed transient improvement of short duration. The palliative effects of testosterone were striking in four cases, but the duration of response was limited. No evidence that testosterone therapy can cure advanced breast cancer was observed, and palliative results can be anticipated in only a relatively small number of patients.

PENICILLIN IN TETANUS
A Clinical Analysis of Fifty-Nine Cases

R. S. DIAZ-RIVERA, M.D.
LUIS R. DELIZ, M.D.
and
JOSE BERIO-SUAREZ, M.D.
San Juan, Puerto Rico

The clinical picture of generalized tetanus has been known for thousands of years; its causative agent was discovered over sixty years ago; almost perfect methods of prophylaxis are known and being practiced, and yet the disease remains as one of the most dangerous infectious complications of wounds, because of the inadequate methods of treatment.

The studies of Abel and his co-workers¹ and Firor and his co-workers² have demonstrated that the value of tetanus antitoxin is limited once the symptoms of the disease are well established, and when an overwhelming amount of toxin is fixed by the cells of the central nervous system the invariable outcome is death.

Even if the outcome of generalized tetanus is always grave, there are patients that respond favorably to the limited but well known therapeutic measures. This is especially true among patients for whom treatment is started before the onset of the serious manifestations of the disease. In spite of early treatment and, at times, heroic measures, the mortality rate of the disease is still too high.

Although judgment of the outcome in tetanus is not always exact, it is known that a short incubation period, the rapid appearance of muscle spasms after onset, frequent and severe convulsions and a poor response to sedation are always signs of a poor prognosis. In these cases the physician is almost at a loss from the start.

In view of the inadequate therapeutic measures available for the management of the disease, the favorable reports on the use of penicillin³ and the demonstration that it is an antibiotic for *Clostridium tetani* *in vivo*,⁴ we were prompted to give it a fair trial in a large group of cases.

MATERIAL AND METHODS

During a period of twenty months, between July 1945 and March 1947, there were 2,364 medical admissions to the San Juan City Hospital. Fifty-nine (2.4 per cent) of the patients were suffering from tetanus. There were 38 white patients, of whom 26 were male and 12 female, and 21 were Negro, 13 being male and 8 female. The youngest was 8 years old and the oldest

70, with an average age of 22.7 years. There were 2 under 10, 25 under 20, 37 under 30, 49 under 40, 53 under 50, 58 under 60, and 1 was 70 years old.

The incubation period was known in 51 cases, varying between two days and three months. There were 15 with an incubation period between one and five days, 20 between six and ten days, 8 between eleven and fifteen days, 2 between sixteen and twenty days and 6 over twenty-one days. The average incubation period for the whole group was eight and four-tenths days and for the cases with fatal outcome five and seven-tenths days.

The portal of entry was discovered in 57 instances: the feet in 24, the leg in 8, the hand in 7, the arm in 7, the mouth in 2, the anus in 2, the uterus in 2, the abdominal wall in 2 and the penis, thigh and cheek in 1 instance each.

The nature of the lesion was evident in 54 cases. Puncture wounds due to rusty nails, splinters of wood, broken glass, tin cans and rusty wire were noticed in 17 cases. Chiggers were responsible for infection in 7 cases, lacerations in 5, abrasions in 5, ulcerations in 4, incised wounds in 3, abortions in 2 and hypodermic injections in 2 (a liver injection in the arm and an

injection of fibrinogen in the abdominal wall). In 2 instances anal fissures were discovered and thought to be the portals of entry in the absence of any other open lesion. In another, a carious tooth was picked with a blunt instrument and in a few days the disease developed. Extraction of a tooth, an abscess of the cheek, a burn, a contusion, a human bite and a surgical wound for a herniotomy were each responsible for a case.

The disease in 56 of the cases was classified as generalized tetanus and in 3 as cephalic tetanus. No cases of the local disease were observed. Twenty-nine patients had convulsions before admission; this symptom developed in 12 after hospitalization (in 5 within the first twenty-four hours, 6 within forty-eight hours and 1 within seventy-two hours after admission), while 18 never suffered from this symptom.

The time between the onset of symptoms and the occurrence of convulsions or muscle spasms was known in 35 cases—in 10 within the first day, in 6 within two days, in 3 within three days, in 3 within four days, in 12 within five days, in 1 within six days, in 2 within seven days, in 2 within eight days, in 3 within nine days and in 1 each within thirteen, sixteen and twenty days. Two of the 12 patients in whom convulsions developed after admission died from the disease.

The most frequent clinical observations on admission were stiffness of the jaw, trismus, dysphagia, rigidity of the neck, abdominal rigidity, restlessness, back pain,

muscularly as well. The portal of entry, when accessible, was debrided and excised when necessary, after the infiltration of the surrounding tissues with 20,000 units of antiserum. The lesion was left open and treated locally with hydrogen peroxide compresses. Daily intramuscular injections of 5,000 to 10,000 units of antiserum were given for the next three days. Forty-two patients received more than 250,000 units of the antiserum. Two thousand to 4,000 cc. of 5 per cent dextrose in isotonic sodium chloride solution was given intravenously in accordance with the patients' needs for hydration, and an indwelling stomach tube was left in situ for the nutrition of the most seriously ill patients. Phenobarbital sodium was given hypodermically in doses of 2 grains (0.13 Gm.) or more every two to three hours for the control of convulsions. In some cases we had to resort to a mixture of ether and oil given by rectum to relieve the painful convulsions. Treatment with penicillin, in doses of 15,000 to 20,000 units intramuscularly every three hours, was started on admission, and the total unitage of the drug was not limited.

RESULTS

There were 12 patients who died and 47 who recovered, with a gross mortality rate of 20.3 per cent. The average hospital stay for the whole group was nineteen days and for the patients that died five and five-tenths days. The average length of life after the onset of symptoms in the cases in which the disease was fatal was eleven and six-tenths days. Four lived for seven, ten, twenty-one and thirty-six hours, respectively, after admission. These did not receive the full benefit of treatment. Only 8, therefore, could be considered as hospital deaths, the hospital mortality rate being 13.5 per cent. The 59 patients received an average total of 1,800,000 units of penicillin, while the 12 that died received an average of 796,000 units. It is known that the clinical improvement in most established infections

usually occurs within eighteen to seventy-two hours after the beginning of treatment with penicillin. Granting that the drug was beneficial, 8 patients were given full chance for improvement or recovery, 2 a partial chance and 2 were not given enough drug to benefit them at all. The mortality rate in spite of efficient penicillin therapy was, therefore, 17.6 per cent (10 deaths) (table 2). If the total unitage of the drug were considered as essential in the control and cure of the infection, perhaps the relatively small amounts given to 4 of the patients would explain the fatal outcome, but other factors may have been responsible, since much heavier doses failed to save the life of the other 8. The average amount of tetanus antitoxin administered to the 59 patients was 260,000 units, while the patients in whom the disease terminated fatally received 251,666 units. The difference was so slight that the amount of antitoxin had little to do in the issue of life or death. It was evident that as an adjuvant penicillin produced beneficial effects, as demonstrated by the low mortality rate. Obvious benefit from the drug was recorded among 11 patients with bronchopneumonia complicating tetanus. Seven of these recovered, and 4 died.

The duration and frequency of the convulsions were not benefited by either penicillin or tetanus antitoxin. Two of the patients who died had received large doses of antitoxin before the onset of convulsions, and in both the disease was classified as mild. It is evident that in these 2 patients the outcome could not be determined on admission.

Among the 26 white male patients in this series only 2 died, yielding the surprisingly low mortality rate of 7.6 per cent, while of the 13 Negro male patients 30.8 per cent died. Of the 12 white female patients 5 died, with a mortality rate of 41.7 per cent, while of the 8 Negro female patients 1 died, with a mortality rate of 12.5 per cent. Thus, the mortality rate among the white persons was 15.4 per cent and among the Negroes, 30.0 per cent (table 3). This difference in the mortality rate in the two races is unexplained, since there was no gross difference in the incubation period, nature of the lesions and portal of entry in the two groups. By the same token, the difference in the mortality rate of male patients as compared with that of female patients lacks an explanation.

From the data presented in this paper it appears that tetanus is a more serious illness among patients older than 50 and younger than 10, as evidenced by a 50 per cent mortality rate among those older than 50 and

TABLE 3.—Mortality Rate: Sex and Race

	Male	No. of Deaths	Per-centage	Female	No. of Deaths	Per-centage

Negro.....	13	4	30.8	8	1	12.5
Total.....	39	6	15.4	20	6	30.0

younger than 10, as compared with 15.5 per cent among those between 11 and 50 years of age, but there were only 2 patients younger than 10 and 6 older than 50. Perhaps a larger series would have yielded different results (table 5).

Six deaths (40 per cent) were recorded among the 15 patients with an incubation period of five days or less, 3 (15 per cent) of the 20 with an incubation of six to ten days and only 1 (12.5 per cent) among those with an incubation period of more than ten days. Two of the patients with no known periods of incubation died from the disease, but the rapid clinical course in these

2 suggests that it was relatively short (table 4). Among the 10 patients in whom convulsions appeared within twenty-four hours after onset of the disease, 6 (60 per cent) died; within the first forty-eight hours 3 (50 per cent) died, and within seventy-two hours 2 (33.3

TABLE 4.—Incubation Period and Mortality Rate

per cent died. Information was not obtained in the other 3 fatal cases. These observations substantiate the relationship of a high mortality rate with a short incubation period and a rapid onset of convulsions (table 6).

The mortality rate among those patients with a portal of entry in the lower extremity was 13.3 per cent, of those in upper extremities 29 per cent, in the trunk

pneumonia and in 1 to extreme dehydration. Severe serum sickness contributed to 1 death. Milder reactions to antitetanic serum were seen in 4 patients who recovered. No causative agent was demonstrable in the cases of bronchopneumonia, but we suspect that in the fatal cases either the causative agent was penicillin resistant, the drug was not administered in large enough doses to effect a cure or these may have been instances of severe aspiration pneumonia.

COMMENT

The potential value of penicillin in the treatment of tetanus has been explored by various investigators, and the results have been controversial. An exact evaluation of the usefulness of the drug is at present impossible, since few planned clinical studies have been made and the great majority of reports in the literature are based on small groups of cases.

A clinical study of 59 cases of tetanus is hereby presented, in which certain conclusions are justified. All the patients received large amounts of penicillin and antitetanic serum and were benefited by other well known therapeutic measures in the accepted treatment

with improvement, but the value of this procedure is questionable. In our second case oxygen was bubbled into the uterus, but this was to no avail (table 7).

Puncture wounds yielded a mortality rate of 11.8 per cent, chiggers 14.3 per cent, lacerations 20 per cent, abrasions 0 per cent, ulcerations 50 per cent, incised wounds 33.3 per cent, endometritis 50 per cent and hypodermic injections 50 per cent. As a rule the lesion looked inoffensive, and it appears that for that reason none of our patients received prophylactic inoculations after injury (table 8).

The actual cause of death was known in the 12 fatal cases. In 7, it was due to respiratory paralysis and overwhelming toxemia, in 4 to complicating broncho-

of the disease. There were patients of almost all ages, and there was a fair sampling as to sex and race. It being a planned study, precautions were taken that all patients were handled as similarly as possible and that the most exact information was obtained. Twelve patients died, yielding a gross mortality rate of 20.3 per cent. Of these, only 10 received adequate amounts of penicillin to guarantee full benefit, with a mortality rate of 17.6 per cent. Such a low mortality rate among a large group of cases of tetanus is difficult to explain, when in the best of institutions the mortality rate may be as high as 50 to 60 per cent. It may be suggested that Puerto Ricans are naturally resistant to the disease.

That this is not true has been demonstrated by Francisco,⁵ who reported a mortality rate of 58.1 per cent in a large group of natives of Puerto Rico receiving tetanus antitoxin as the only form of treatment for tetanus.

5. Francisco, R.: A Clinical and Epidemiological Study of Tetanus in Puerto Rico: A Study of One Hundred Cases Seen at the Arecibo District Charity Hospital in a 2½ Year Period, *Clinics* 3: 373-414, 1944.

There is abundant experimental proof to deny any favorable effects of large amounts of antitoxin in severe well established generalized tetanus. An analysis of our data shows that tetanus antitoxin not only is useless in relieving the convulsions but also failed to prevent the symptom in 12 of the patients hospitalized early in the course of the disease. On admission, these patients appeared only moderately ill, and the disease was labeled as mild tetanus. It seems that some time elapsed between the fixation of the toxin by the cells of the central nervous system and its diffusion to the neuromuscular end organ and that the quantity of toxin released was large enough to produce symptoms of such severity as to cause the death of 2 of these patients. This tends to demonstrate that judgment as to the outcome of tetanus is inexact when based on the presence or absence of convulsions and that in some cases the issue of life or death is not affected by the administration of antitoxin, no matter what the quantity or how early in the course of the disease it is given. It is emphasized that the mortality rate among the 12 patients in whom convulsions developed after hospitalization (16.6 per cent) approached that for the whole group (20.3 per cent).

It appears that penicillin is useless in the prevention of the diffusion of the tetanus toxin through the tissues or its fixation by the nerve cells. By the same token, it does not relieve or prevent convulsions in already established tetanus.⁶ However, the favorable results obtained in this series of cases indicate that it is a valuable adjuvant in the treatment of the disease in combination with the other accepted measures. Penicillin has been shown to be an antibiotic for *Clostridium tetani* in vitro, and this property of the drug has been confirmed in vivo by Weinstein and Wesselhoeft,⁴ who noted the disappearance of the tetanus bacilli from the wounds of 2 patients twenty-four hours after the administration of the drug.

Perhaps the low mortality rate reported in this paper could be explained by this property of the drug, which by paralyzing the multiplication of *Clostridium tetani* reduced or prevented further production of toxin. The maintenance of a proper blood level of the drug may have been beneficial in preventing secondary bacterial infections. That it was efficient in curing bacterial complications incident to the disease is evidenced by the

recovery of 7 of our 11 patients suffering from bronchopneumonia. The failure of treatment with the drug in the fatal cases may have been due to a penicillin-resistant strain of bacteria, to small doses of the drug or to instances of aspiration pneumonia.

Definite conclusions as to the value of penicillin in tetanus must await more extensive studies in larger groups of cases. To deny its value on the basis of a high mortality rate among a small number of cases would perhaps be harmful, especially when the majority of the patients who died had not received the full benefit of the drug.⁷

It should be reemphasized that the most accurate prognostic signs of the disease are the length of the incubation period and the rapidity of appearance of muscle spasms after the onset of the disease and that, in spite of the favorable results reported in this paper, penicillin would be useless in the treatment of the disease if not used in conjunction with supportive measures for the maintenance of proper hydration and electrolytic balance, good nutrition, efficient sedation, neutralization of the free toxin with tetanus antiserum and proper debridement of the portals of entry if accessible.

SUMMARY AND CONCLUSIONS

On the basis of our observations of 59 patients with tetanus, we conclude that penicillin is a useful adjuvant in the treatment of the disease. The gross mortality rate was 20.3 per cent; the mortality rate among those patients that received a fair trial with penicillin being 17.6 per cent.

The favorable action of the drug may be attributed to its antibiotic property against the tetanus bacillus, that, by hindering its growth and multiplication, eliminated or paralyzed the production of the toxin.

Penicillin may also act as an antibiotic for other bacteria, preventing or curing already established complications, such as bronchopneumonia.

Penicillin is considered useless in the prevention of convulsions and in the elimination of the free toxin in the body or the already fixed toxin in the cells of the central nervous system.

The administration of large amounts of antitoxin is recommended to neutralize the toxin that is free in the body or being produced by *Clostridium tetani*.

The antitoxin is useless in preventing the onset of or in eliminating the convulsions of tetanus when present.

It appears from the analysis of the data of 12 of our patients that some time elapses between the fixation of the tetanus toxin by the nerve cells and its diffusion to the tissues resulting in convulsions.

The presence of convulsions in tetanus is not a measure of its severity, and the formulation of a good prognosis in the absence of this symptom may be erroneous.

Debridement of infected wounds, maintenance of proper hydration and electrolyte balance, good nutrition and sedation are considered as important as the administration of antitoxin or penicillin in the treatment of tetanus.

It is reemphasized that the mortality rate in tetanus is higher in the cases with short incubation period and rapid onset of convulsions.

The early recognition of the disease and the rapid institution of treatment with all available measures may have been contributory to the low mortality rate reported in this paper.

CARCINOMA OF THE BREAST

C. D. HAAGENSEN, M.D.
New York

This article is the fifteenth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment.

Cancer of the breast is one of the great diseases with which physicians have struggled since time immemorial. For the modern physician, however, cancer of the breast is a greater challenge than it was to his colleagues of even a generation ago, because today there are improved diagnostic methods that often make it possible to recognize the disease while it is still early, and there are new therapeutic methods that give better control over it. Unfortunately, this new knowledge has not as yet been fully digested and applied. There is a long way to go in the education of both the medical profession and the public. In a recent series of cases coming to the

Presbyterian Hospital in which a careful study of the manner of diagnosis was made, it was found that wrong medical advice had been given to 27 per cent of the patients by the first physician whom they consulted. Surely here is an opportunity for better education of physicians.

The patients themselves must, of course, bear a measure of responsibility for delay. Many women delay consulting a physician for a long time after they discover that they have a tumor of the breast: ignorance, negligence and fear all play a part in this delay.

I believe that women should be educated in college hygiene courses, and by every other available method of propaganda, to examine their own breasts once a month, in the middle of the menstrual cycle when mammary engorgement is at a minimum. They should be taught to consult a physician promptly whenever they feel a lump or whenever discharge from the nipple or any asymmetry of the breast is discovered.

From the Department of Surgery and the Laboratory of Surgical Pathology of the School of Medicine of Columbia University.

THE PROBLEM OF DIAGNOSIS

FREQUENCY OF CANCER OF THE BREAST

The first step toward better diagnosis of cancer of the breast is a full realization of its frequency. According to Levin's¹ recent morbidity data for New York state the breast is by far the most frequent site for cancer in either sex (fig. 1). In women it is almost

Fig. 2.—Palpation of the supraclavicular regions.

twice as frequent as any other type of cancer. About 4 per cent of all adult women contract the disease. It is rare before the age of 25, but from then on its incidence increases throughout the whole life span.

These facts should produce in the mind of every physician an alert suspicion of the presence of cancer of the breast whenever anything abnormal is seen or felt in the course of examination of the breasts. Their examination is an important part of every physical examination. The value of careful routine examination of the breasts has been well established in our clinic, where 3.4 per cent of the total number of cancers of the

Fig. 3.—Palpation of the axilla.

breast were detected by such routine examination of patients who came to consult regarding some wholly irrelevant symptom.

EXAMINATION OF THE BREAST

A good deal of the success with which early cancer of the breast is detected depends on the care taken in

1. Levin, M. L.: Cancer Morbidity in New York State, personal communication to the author.

the examination of the breasts. The examiner must study the breasts as a separate step in his complete physical examination. If he merely passes his hand over his patient's breasts while she sits erect, as he prepares to examine her heart and lungs, he will often miss lesions of the breasts. An adequate examination

Fig. 4.—Inspection of the breasts with the arms at the sides and with the arms raised.

is a well ordered procedure including several different steps and requiring ten or fifteen minutes even when no abnormality is found. When the examiner finds something that arouses his suspicion that the breast may be diseased still other maneuvers are required.

I have found it advantageous to develop a routine for examining the breasts because following an orderly routine guards against overlooking important details.

The procedure begins with examination of the supraclavicular and axillary regions. The patient sits on the table facing the examiner, with her legs over its side. The supraclavicular regions are conveniently palpated as the examiner stands behind the patient (fig. 2). In the examination of the axilla (fig. 3) it is essential that the pectoral muscles be relaxed. To achieve this the examiner supports the patient's arm on one of his

Fig. 5.—Palpation of the breast. The patient lies supine with a small pillow under her shoulder on the side being examined.

own. He then palpates with the tips of the fingers of his other hand. The more gentle his palpation the better he will feel lymph nodes lying against the thoracic wall. Lymph nodes high up in the axilla are difficult or impossible to feel. In obese patients palpation of the axilla is particularly unreliable.

Not only the number, but the consistence and mobility of the axillary lymph nodes should be noted.

They may be fixed to the underlying chest wall or the overlying skin. My colleagues and I have found it useful to attempt to measure the size of the largest axillary node, estimating transverse diameter in centimeters.

Palpation is unfortunately very inaccurate in determining whether axillary lymph nodes contain metastases. In the Presbyterian Hospital series of cases in which the examiner thought these nodes not to be involved 44 per cent were found by microscopic examination to contain metastases. On the other hand, in the cases in which the examiner made a clinical diagnosis of axillary metastases, 15 per cent of the patients proved not to have them.

The next step in our routine is a critical inspection of the breasts themselves, first with the patient's arms at her sides and then with the arms raised high above her head (fig. 4). The examination must be conducted in a good light, for nuances of light and shade and slight changes in contour of the breasts are of great importance and may be missed if the lighting is poor. The examiner compares the contour of the two breasts,

Fig. 6.—Carcinoma of the upper central part of the breast with pronounced retraction signs. Note the deep dimple over the carcinoma, the contraction of the areola and the pulling up of the nipple toward the lesion.

following it from the anterior axillary fold to the midline on each side. An indentation or a bulge in this contour often betrays the site of a lesion. He compares the height of each breast on the chest wall and their relative size.

The shrunken breast of advanced slowly growing carcinoma, or the generally enlarged edematous breast of acute carcinoma are at once obvious, but the subtle changes due to earlier lesions are not so evident.

It will sometimes be noted that one breast is slightly larger than the other, yet perfectly symmetric with its mate. This mere disparity in size is often only a developmental defect, and if not accompanied by other signs is no cause for alarm.

The shape and size of the areolas and their comparative level are next studied. The shape of the nipples and the axes in which they point are compared. The surface of the nipples is carefully inspected in a search for crusting or erosion.

Inspection completed, the examiner is ready for palpation of the breasts. This is best performed with the patient lying down (fig. 5). For adequate palpation the breast should be balanced on the chest wall, forming an even layer spread out over the thoracic cage. To achieve this we elevate the chest on the side of the breast being examined by placing a small pillow under

the shoulder. If the breast is allowed to fall to the patient's side, folding on itself, the examiner may mistake its folds for abnormalities.

The whole extent of the breast is now gone over with the tips of the fingers. It should be kept in mind that the breast tissue often extends over a wide area. A thin layer of it may reach the midline of the sternum medially, the lower edge of the clavicle above and the edge of the latissimus dorsi muscle laterally. Small subcutaneous tumors near these outer limits of the breast may be mistaken for benign subcutaneous lesions not associated with the breast when in fact they are carcinomas of the breast. The axillary prolongation of the breast extends high into the axilla in some subjects, and carcinoma arising in it is commonly mistaken for lymphosarcoma or adenitis of the axillary lymph nodes.

In palpating the breast a little talcum powder on the skin diminishes friction and may add to the accuracy

It has been our experience that careful palpation of the breast, carried out according to this plan, will reveal a carcinoma of the breast even when it measures only 4 or 5 mm. in diameter. The hardness of the tumor and its relative fixation in the area of breast tissue in

Fig. 7.—Carcinoma of the upper outer sector of the breast. Note the broad dimple over the carcinoma and the pulling up of the nipple toward it.

of tactile perception of the consistence of breast tissue. Gentle palpation is not only more informative than rough examination; it is a necessary precaution against the hazard of causing metastasis. We try to emphasize this danger by sharply limiting the examination of women with carcinoma of the breast by students on our wards.

Although palpation in the supine position is certainly the best method of detecting abnormalities in most parts of the breast, there is one area which it is wise also to palpate between the fingers of both hands with the patient sitting up. This is the subareolar and nipple region. In this central area where the ducts converge to enter the base of the nipple the breast structure is looser and less dense. In breasts which are thick and relatively firm in texture, the comparatively dense breast tissue forms a sort of ledge around the softer subareolar region. The cephalad portion of this ledge is not infrequently mistaken for a tumor. On the other hand, a real tumor of small size situated in the softer subareolar area may be almost impalpable in the supine position, although when examined between the fingers with the breast dependent the tumor is readily felt.

Fig. 8.—Carcinoma of the lower inner sector of the right breast. With arms at the sides no asymmetry is seen.

which it lies, making it impossible to move it without carrying along the surrounding breast tissue, are the features which most often suggest that it is a carcinoma. Most carcinomas are not sharply circumscribed; the edge of the lesion merges with the surrounding breast tissue which it infiltrates. This makes a carcinoma difficult to measure precisely.

Fig. 9.—Carcinoma of the lower inner sector of the right breast. With arms raised an indentation is seen at X.

But consistence and mobility and circumscription are by no means reliable indications of the nature of a tumor of the breast. Papillary carcinomas and colloid carcinomas may be soft, while a calcified fibroadenoma may be as hard as stone. There is a type of strikingly well circumscribed carcinoma which we call in our laboratory the *solid circumscribed type*, which may strongly suggest a cyst or a fibroadenoma. On the other

A maneuver which is often helpful in demonstrating retraction signs in a carcinomatous breast is that of pectoral contraction. While in the sitting position the patient relaxes and rests her hands on her hips, giving the examiner an opportunity to compare the relative

Fig. 18.—Carcinoma of the outer part of the left breast. Breasts symmetrical in erect position.

heights of the lower edge of the breast and the level of the areola on each side, and to look for retraction signs over the tumor. The patient is then asked to press her hand against her hip, contracting her pectoral muscles, first on the normal and then on the diseased side. The normal breast is pulled upward slightly by this action, but the carcinomatous breast often rises sharply as compared with its mate. The breast as a whole may be abnormally elevated, or merely the sector of the breast in which the carcinoma is situated. This abnormal elevation occurs, of course, because the fibrosis in the carcinomatous area ties it down to the underlying pectoral fascia. When contraction of the pectoralis major elevates the pectoral fascia the carcinomatous area in the breast is pulled up with it. This is a *relative*, not a *solid*, fixation, as when carcinoma in a more advanced stage becomes immobile on the chest wall.

Fig. 19.—Carcinoma of the outer part of the left breast. In forward bending position there is flattening of the lateral contour of the breast at X.

When the carcinoma is solidly fixed, pressing the hand against the hip of course produces no elevation of the breast at all.

Pectoral contraction also brings out other retraction signs—deviation of the nipple toward the carcinoma, and lines and dimples in the skin over it. Figures 13 and 14 demonstrate this pectoral contraction maneuver

in a patient with carcinoma in the outer upper part of the breast. Figure 13 shows the patient with her arm relaxed: no definite dimpling is seen in the skin adjacent to the carcinoma indicated by the circle. But when her arm is pressed against her side in figure 14 a whole series of lines and furrows appear in the skin.

Fig. 20.—Carcinoma of the upper central part of the left breast. Left areola and nipple elevated.

Another method of demonstrating the presence of a relative degree of fixation of the carcinomatous area in the breast to the pectoral fascia is to test the lateral

Fig. 21.—Carcinoma of the upper central part of the left breast. The elevation of the areola and the nipple, and the breast as a whole, are accentuated by forward bending.

mobility of the breast while the patient lies supine, as shown in figure 15. In the gentlest possible manner the sector of the breast containing the tumor is moved transversely across the chest wall between the fingers of the examiner's two hands, first with the arm relaxed, and then with the arm pressed against the hip to contract the pectoral muscles. In patients in whom the diseased area is relatively fixed by fibrosis to the underlying pectoral fascia the breast can be moved freely while the arm is relaxed, but motion is sharply checked when the pectoral muscles are contracted.

Another procedure of great value in demonstrating retraction signs in the breast is the forward bending

maneuver. I learned of it from the late Hugh Auchincloss, who used it with striking effect. The patient is asked to bend far forward from the hips, keeping her chin up and extending her hands forward to the examiner who supports them as he sits before her. In this

Fig. 22.—Deviation of the axis of the left nipple downward and outward toward a carcinoma in the lower outer sector of the breast.

position normal breasts fall freely away from the chest wall and are perfectly symmetrical. But if a carcinoma is present in one of them, even though the growth be small, the fibrosis which accompanies it will usually fix in some degree the diseased breast to the chest wall and produce an asymmetry which careful inspection from the side or from the front will detect. Over and over again we have seen carcinoma in the breast betrayed by asymmetry demonstrated by this maneuver, although there were no other retraction signs. Figures 16 and 17 show a good example of the value of forward bending. There was a small firm carcinoma beneath the areola as indicated by the circle, but no asymmetry was evident as the patient sat with her arms at her sides.

Fig. 23.—Deviation of the axis of the left nipple upward and outward toward a carcinoma in the upper outer sector of the breast, accentuated by forward bending.

When she bent forward, however, the nipple and medial part of the areola were pulled deeply up into the breast. No observer would miss this distortion.

The change in the contour of the breast which carcinoma produces is much less apparent in some cases. The patient shown in figures 18 and 19 illustrates this fact. Here forward bending revealed only a slight

flattening of the lateral contour of the left breast in the area marked X adjacent to the carcinoma indicated by the circle. There was no dimple in the skin over this lesion.

In his search for retraction signs the examiner should pay special attention to changes in the areola and nipple. The horizontal level of the areola and nipple is often elevated by a carcinoma in the upper half of the breast. The areola may be narrowed and distorted so that it points toward the carcinoma. All these changes are illustrated in figure 20. They were accentuated when the patient bent forward as shown in figure 21.

Deviation of the axis in which the nipple points is a subtle variety of retraction sign. The fibrosis in and about the carcinoma pulls on the duct system and tilts the nipple so that it points toward the carcinoma. Figure 22 shows deviation of the axis of the left nipple downward toward the carcinoma indicated by the circle in the lower breast. Figure 23 shows upward deviation

Fig. 24.—Flattening and broadening of the right nipple due to a carcinoma in the central part of the breast.

of the left nipple toward a carcinoma indicated by a circle in the upper part of the breast. In this figure the deviation is accentuated by forward bending.

When the carcinoma involves the area more or less directly beneath the nipple the fibrosis shortens the whole duct system and pulls the nipple inward. This process may show itself merely as flattening and broadening of the nipple (fig. 24) on the carcinomatous side as compared with its mate. The nipple loses its elasticity and cannot be pulled out like the uninvolved one. As the fibrosis progresses the nipple becomes flatter and broader until, in some instances, it finally retracts beneath the surface of the surrounding areola (fig. 25).

Flattening or retraction of the nipple due to carcinoma should not be confused with mere inversion of the nipple, a condition seen in a good many women with no disease of the breast. Inversion of the nipple may be bilateral or unilateral. The patient will usually say that the inversion has been present for many years and that it interfered with nursing. Instead of protruding in the normal way the inverted nipple has the appearance of a sulcus, into the bottom of which the ducts open. Inverted nipples can often be pulled out. They are not broadened and thickened and fixed, like the retracted nipple of carcinoma.

The fibrosis following an abscess sometimes distorts the nipple, changing its axis or inverting it. The history and the presence of a scar should enable the examiner to interpret such changes correctly.

The carcinomas of the breast in which a careful examination fails to reveal any of the retraction signs described are few indeed. In my experience these few have been either the solid circumscribed type or well differentiated types. Both of these varieties seem on occasion to produce less fibrosis in the surrounding breast than most carcinomas, and therefore less retraction.

Erosion.—Erosion of the surface of the nipple is an important sign of carcinoma. Even when it is only 2 or 3 mm. in diameter it warrants a presumptive diag-

is flattened and finally destroyed by the process, which extends onto the areola and then over the skin of the breast. This type of carcinoma is relatively somewhat less malignant than other forms of carcinoma of the breast, and cure may be achieved even when the erosion

Fig. 25.—Side view of the left nipple showing it retracted below the level of the areola due to a central carcinoma of the breast.

nosis of the Paget type of carcinoma. Modern histologic studies have shown that what Sir James Paget thought was a "disease of the mammary areola preceding cancer of the mammary gland" is in fact actual involvement of the nipple epidermis by carcinoma cells. In Paget's erosion of the nipple meticulous microscopic search of the breast will always reveal somewhere in it a primary carcinoma whose cells have grown along the ducts to reach the surface of the nipple. These so-called Paget cells have a peculiar predisposition to grow only within the epidermis (fig. 26). Not all erosions of the nipple, of course, are carcinomatous, for inflammatory and trophic eczema-like lesions do occasionally develop in the nipple and areola. But the percentage of nipple erosions that are carcinomatous is so high that biopsy of the lesion and microscopic proof of its nature are always necessary. The typical Paget erosion is a crusted or moist and granular area on the surface of the nipple (fig. 27). It dries up and seems to heal over from time to time but soon breaks open again, enlarging slowly but steadily. The nipple

Fig. 26.—Paget carcinoma cells in the epidermis of the nipple.

has been present for years and has involved a large area of the skin over the breast, as in the patient shown in figure 28.

Discharge.—A discharge from the nipple is, of course, a sign of abnormality in the breast. This may be physiologic and harmless, or pathologic and an indication of inflammation or of epithelial proliferation. The character of the discharge is an important distinguishing feature.

Fig. 27.—Paget's erosion of the nipple—an early lesion.

A discharge which has the consistency and color of milk is usually just that. Occasional women continue to secrete a small amount of milk for months, and in rare cases for years, after lactation would normally have ceased. We do not yet have enough understanding

of the hormonal control of lactation to know the physiologic mechanism in these cases. This kind of nipple secretion is usually bilateral. The few drops of milk that accumulate in the duct system of such a breast do not usually escape spontaneously but appear only when the breast is squeezed or the nipple is stimulated. Such a discharge from the nipple is harmless.

Low grade inflammatory processes, developing in the subareolar portion of the breast close to the larger ducts, sometimes break into a duct which provides a channel for the escape of secretion. This type of inflammatory discharge has the gross character of pus, and its nature can be confirmed by making a smear of it and examining it microscopically. Although recurring or persisting infection in the breast is notoriously difficult to eradicate, perhaps because of the poor blood supply and fatty character of the breast tissue, attempts to provide adequate surgical drainage should be made in these cases. When the abscess cavity is opened it is wise to excise a small piece of tissue for microscopic examination, to rule out the possibility of unsuspected carcinoma.

Fig. 28.—Extensive Paget's disease with destruction of the nipple.

A thin, yellowish, brownish, reddish or frankly bloody discharge from the nipple is almost always a sign of epithelial proliferation. This kind of discharge usually escapes spontaneously and stains the patient's brassière. In the great majority of cases it is due to an intraductal papilloma growing in one of the larger ducts in the subareolar region, and not to carcinoma. The dilated duct containing the papilloma can usually be detected by careful palpation as a small cordlike or rounded tumor beneath or close to the areola. Pressure on it produces a drop or two of secretion from the opening of the involved duct on the surface of the nipple. Such a lesion should always be explored surgically, and the diseased duct or ducts excised. Microscopic examination will confirm the benign nature of the papilloma and rule out carcinoma.

If the papillary process is situated some distance out in the breast tissue away from the subareolar region,

or if it has grown to form a tumor of considerable size, it is wise to make a biopsy of the lesion before attempting to remove it, because such growths are often papillary carcinomas.

If, in a patient with a history of a yellowish, brownish or bloody discharge from the nipple, careful palpation

Fig. 29.—Infra-red photograph to show dilated subcutaneous veins in carcinoma of the left breast.

does not reveal any tumor or any point where pressure elicits the discharge, the surgeon should reexamine the breast after a few days, cautioning the patient against squeezing the breast in the meantime. During this interval the secretion will have an opportunity to accumulate in the diseased duct, and reexamination may localize it.

When examination still fails to reveal the source of the discharge, the subareolar and central area of the breast should be explored surgically. Although difficult for the surgeon, such an exploration is justified

Fig. 30.—Extensive edema of the skin in carcinoma of the breast.

because this type of discharge from the nipple is in a small percentage of cases a sign of carcinoma.

Only about 5 per cent of carcinomas of the breast are, in fact, accompanied by a discharge from the nipple. In most of these patients there is also a palpable tumor which has the clinical characteristics of a carcinoma.

The discharge is more often frankly bloody than yellowish or brownish. Even though it is infrequently the only sign of carcinoma, such a discharge from the nipple should never be dismissed lightly. Its cause must be searched for and its nature proved.

Abnormal Circulatory Relationships.—Retraction signs are not, of course, the only clinical signs produced by carcinomas of the breast. There is a group of

Fig. 31.—Edema limited to the skin of the areolar region in carcinoma of the right breast.

clinical signs produced by abnormal circulatory relationships in the breast. Carcinoma growing in the breast causes an increase in the blood supply to the part. This not infrequently produces hyperemia of the skin, which is abnormally warm and sometimes reddened. The subcutaneous veins over the upper part of the breast may be visibly dilated. Infra-red photographs bring out this dilatation in a striking manner (fig. 29). At operation the internal mammary vessels (the chief blood supply to the breast) at the intercostal level corresponding to the carcinoma will often be seen to be abnormally large. It may be argued that prominence of subcutaneous and intercostal veins might be due to venous obstruction, but we have repeatedly seen it in cases in which there was no evidence at all of obstruction of the axillary vein.

Edema of the skin of the breast due to blocking of the subdermal lymphatics is an important sign of carcinoma in an advanced stage. Lymph accumulates within the skin until it is several times its normal thickness, and causes abnormal separation and deepening of the orifices of the cutaneous glands (fig. 30).

When the area of edema is small, as in the case shown in figure 31, it easily escapes detection unless carefully looked for. It usually begins as in this patient, in the skin within the areola, or just caudad to it; that is, in the most dependent part of the breast. This is regularly the site where edema appears when the carcinoma is situated deep in the center of the breast, but it may also be the earliest location of edema when the carcinoma is situated in the periphery of the breast. We have seen edema appear just below and medial to the nipple when the carcinoma was a small one located in the extreme upper outer part of the breast.

This tendency of edema to develop in the areolar region is probably due to the fact that carcinoma of the breast tends to spread, in its late stages, in a retrograde fashion along the main lymphatic pathways. These radiate from the areolar region.

There are, of course, other cases in which the edema first appears in the skin immediately over a carcinoma situated more peripherally in the breast. In such cases the skin is usually somewhat adherent to the underlying tumor, and it seems probable that the lymphatics of

the skin are obstructed by direct retrograde invasion from the surface of the growth outward.

We have been much interested in the mechanism by which edema of the skin is produced, and we have made a special effort over a period of years to study the skin histologically in these cases. In interpreting the findings the first requisite, of course, is an appreciation of the normal arrangement of the lymphatics in the skin. There are no lymphatics in the epidermis itself. In the corium, however, there are two networks of them, a narrow-meshed superficial subdermal one which sends branches up around the papillae, and a wide-meshed deeper one made up of broader channels equipped with valves which communicate by means of vertical branches with the subdermal lymphatics. Our histologic studies of edematous skin have led us to the conclusion that the process begins with the appearance of embolic masses of carcinoma cells in the deep network of lymphatics in the corium. We believe that the mechanism by which extension takes place is at first embolic, rather than one of continuous permeation, because we have often seen the picture illustrated in figures 32 and 33. Here, in edematous skin, the deeper lymphatics are dilated and contain unmistakable tumor emboli. As the edema progresses both the superficial and deep lymphatic vessels become solidly choked with tumor cells, and at this advanced stage of the process permeation is probably the predominant mechanism by which the disease extends.

These signs of disturbed circulation in the breast are, of course, also seen in infections in the breast, both

Fig. 32.—Photomicrograph of edematous skin in carcinoma of the breast, showing carcinoma emboli in dilated subdermal lymphatics.

in acute abscesses and in low grade chronic infections. They are not as distinctive of carcinoma as the retraction signs. Both classes of signs, moreover, may be produced by entirely benign lesions.

Transillumination.—Transillumination of the breast has been emphasized by some clinicians, but we have found it to be of such limited usefulness that we do

not employ it routinely. A papillary cystadenoma containing bloody fluid, situated in the subareolar area of a dependent breast, will show up well in transillumination as a sharply circumscribed entirely opaque shadow. But even when it gives this picture transillumination does not rule out carcinoma and further diagnostic steps are necessary.

Röntgen Examination.—Examination of the breast by roentgen rays to show changes in soft tissue density is not, in our opinion, of any definite value, and we do not employ it. The injection of the ducts of the breasts with an opaque medium for roentgen study seems to us a dangerous procedure. The ducts may contain carcinoma, and injection may distend and rupture them and force carcinoma cells into veins and lymphatics.

All of the refinements of clinical diagnosis which I have described may, of course, be said to be of academic importance, because one cannot lay down absolute rules regarding the diagnostic significance of even the most

Fig. 33.—Higher power view of dilated subdermal lymphatic vessel containing carcinoma emboli.

reliable clinical signs. The surgeon who performs a radical mastectomy must be absolutely certain of his diagnosis, and clinical signs give such security only when they are well developed and when they are interpreted with an extensive background of experience. In most cases the surgeon will wish to rely on the microscopic proof of the presence of carcinoma, for he knows that there are a whole series of benign lesions of the breast which simulate carcinoma more or less closely. A low grade abscess, traumatic fat necrosis, a cyst whose contents have in part escaped into the surrounding breast tissue and set up an inflammatory reaction, adenosis, myoblastoma—any of these may form a hard tumor in the breast with dimpling of the overlying skin. The surgeon's dilemma is a difficult one. He must have proof of the nature of the lesion with which he is dealing, for his whole plan of treatment hinges on this one fact. The benign lesions require only simple local excision, while carcinoma demands a formidable and mutilating operation which must never be done needlessly.

Clinical Notes, Suggestions and New Instruments

HAZARDS OF CURARE

Presentation of a Case

IRVING SALAN, M.D.

and

DONALD M. CARMICHAEL, M.D.

Orangeburg, N. Y.

With the increase in the various "shock therapies," both in institutions and in the private offices of the nation's psychiatrists, there is bound to be an increase in the absolute number of fractures, pulmonary abscesses and deaths, as well as other complications. The literature is replete with case studies of patients with varied diagnoses who have shown adequate and early response to shock therapy. With the improvement of technique and the institution of electroconvulsive treatments have come refinements in procedure which, on the whole, have tended to ameliorate the complications and to increase the number of patients who are being treated. Electroconvulsive therapy has almost completely supplanted the use of "metrazol" N. N. R. (pentamethylenetetrazol) and is tending more and more to supplant insulin therapy. Patients with the depressions and other affective disorders who respond to "metrazol" therapy respond more quickly and with greater ease to the electrical form of convulsive stimulation. More patients can be treated at the same time, and the safety factor is much greater. No longer does one see the severe fractures previously noted with "metrazol" therapy, nor is it as difficult to gage the amount of electrical potential necessary as it was to gage the amount of chemical to be injected. Few therapists are willing to expose their patients to the greater dangers and the lesser certainty of "metrazol" therapy, when they have at hand the simple, less costly and safer procedure which is possible with the electroshock machine. Although the delusional patient does not respond too well to electroconvulsive therapy, his response seems to be equal to the response to insulin therapy, so that again electroconvulsive therapy is the method of choice.

Fractures still form the basis for the greatest fear in the mind of the therapist, and in order to obviate these he has resorted to manual, instead of mechanical, restraint and hyperextension of the dorsolumbar aspect of the spine. These improvements are still too inadequate to prevent fractures completely in certain patients, e.g., muscular men. In addition, there are those patients whose mental condition is sufficiently severe to warrant convulsive therapy but who have bony changes which increase the chances for fracture. Many attempts have been made to lessen the severity of the convulsion among these persons. They have been sedated or have been completely narcotized with preliminary barbiturate medication by either the oral or intravenous route. Various other anticonvulsants have been utilized, none of which proved adequately effective except curare.

With the introduction of treatment with curare, many patients, who otherwise could not be treated because of fear in the mind of the therapist that fractures might ensue, have been accepted for convulsive therapy, with results which justify the use of this added hazard. Some patients have had treatment continued despite vertebral fractures if the psychiatric prognosis justified continued treatment. The usual procedure is to fix the area involved in a cast and to give an injection with curare prior to the advent of further convulsions. Here, too, the results have been favorable and have justified this comparatively radical procedure. The patients, on improvement or recovery from their mental illness, have usually been asymptomatic regarding the injury to the spine.

Read at the Down-State Psychiatric Meeting of the New York State Department of Mental Hygiene, New York State Psychiatric Institute, April 21, 1948.

REPORT OF A CASE

The following report is of a 25 year old white woman with a diagnosis of dementia praecox, catatonic type, who, because of a right femoral hernia which increased in size with each convulsion, was given curare medication. Although she had been mentally sick for a year and a half prior to treatment, the results of three electrically induced grand mal seizures were sufficiently promising to warrant continued treatment despite the additional hazard occasioned by curare medication. Unfortunately, the patient's reaction to curare was poor, and it was felt that her death, following the ninth treatment, was precipitated by treatment with this drug. The preparation used was a product of E. R. Squibb & Sons, "intocostrin"—curare in aqueous diluent—with a standard concentration.

S. A., the daughter of a shy withdrawn father and an aggressive domineering mother, whose family history revealed no evidence of nervous or mental disease, was admitted to the Rockland State Hospital on Feb. 14, 1946, because she would sit motionless, staring fixedly. She paid no attention to questions asked, but at times would giggle inappropriately. She was subject to delusions and hallucinations and showed apparent defects of insight and judgment. She had recently been discharged from another psychiatric hospital, where she had remained for ten months and had received some electroconvulsive therapy and some insulin therapy, with improvement, which was, however, not maintained. She was discharged from this previous institution in December 1945, with her condition noted as "unimproved." For a period of three months she was kept at home, but, because of the difficulty of caring for her, she was admitted to Rockland State Hospital.

The patient was a wanted child, born by normal spontaneous delivery, after an uneventful pregnancy, on Feb. 25, 1921. Early development was described as having been uneventful until the age of 5. At this time the patient refused to leave her mother long enough to attend kindergarten. She retired more and more from external contacts, daydreamed a great deal and preferred reading to mingling with other children. Despite her propensity for reading, she did poorly in school and lost one or two grades. At the age of 16 she left high school to attend business school. She learned to type and at 18 years took her first job as a typist. She worked intermittently, never holding any job more than several weeks. She continued in this fashion until the onset of her present illness.

Her medical history was uneventful. Menarche appeared at 14 years, without untoward distress. She was somewhat disturbed when her breasts failed to develop and wore brassieres stuffed with cotton to hide this development defect. She never showed interest in boys or approved of cosmetics or bad language. She neither smoked cigarets nor drank alcoholic beverages. During the night of Feb. 2, 1945, the patient awoke weeping uncontrollably. She protested that nothing was wrong and that her behavior was caused by a "bad dream." Thereafter she began to sit around, staring into space, and was apparently depressed. She persistently denied that anything was wrong, but had frequent spells of uncontrollable weeping. On February 15 she was admitted to the New York Psychiatric Institute and Hospital. Physical examination here revealed an asthenic, young adult, white woman with subnormal breast development and a large right femoral hernia in her groin, with a swelling the size of a hen's egg. There was a harsh systolic murmur at the cardiac apex, but the electrocardiogram was normal. All other physical observations were normal, and results of laboratory procedures were negative. Mentally she was listless, showed decreased motor activity and decidedly constricted mental activity. Her emotional reaction suggested tension and depression. She manifested ideas of reference with many persecutory trends—people were watching her and talking about her and accused her of having a love affair and of being a "bad" girl. She blocked in answering questions referring to

sexual matters. The sensorium was intact, but mental grasp and capacity were below normal. The Kent EGY test score was 14 and her intelligence quotient 67. Judgment and insight were very poor.

During her stay at the Psychiatric Institute and Hospital she received ambulatory insulin therapy combined with electroconvulsive therapy, resulting in some well defined improvement. She seemed to be in better contact, was less suspicious and joined with other patients in ward activities. The bizarre hallucinations and delusions which were previously apparent tended to disappear. Unfortunately, she regressed and again became rather seclusive, negativistic and demanding. She showed utter lack of judgment and again manifested auditory hallucinations and delusions. She laughed and wept alternately in response to her hallucinations. Therefore, insulin coma therapy was instituted which was terminated on November 10, at which time the patient had received thirty-three treatments, resulting in twenty-nine comas. She showed no improvement in her mental attitude and was discharged on December 12 as "unimproved."

A few months later this girl was admitted to the Rockland State Hospital. She was given a course of electroconvulsive therapy immediately on admission and received a total of twenty applications, resulting in twenty grand mal seizures, but with no noticeable improvement in her status or condition. The patient visibly deteriorated and became untidy, uncooperative, resistive and mute. She refused to eat and was fed by daily gavage. At the insistence of her parents she was again given electroconvulsive therapy on Oct. 21, 1946. It was noted that, possibly due to inanition, her right femoral hernia increased alarmingly with each convulsion. There was some improvement noted during the first three or four treatments, in that the patient began to eat, was less resistive, was much more communicative and was no longer withdrawn and apathetic. This influenced the decision to continue treatment, with the added safeguard of using curare ("intocostrin"). She received six further convulsive treatments with curare premedication, with observable well defined improvement in her status. Following the ninth intravenous administration of curare and subsequent convulsion, respiration ceased. She was given intravenous intramuscular and intracardial injections of neostigmine compound, nikethamide, epinephrine and caffeine, none of which were helpful. Artificial respiration was given for approximately ninety minutes, but normal respiration and cardiac action could not be reestablished and maintained. Postmortem examination failed to reveal anything unusual, and it was felt that this was indeed a death from respiratory paralysis due to treatment with curare. It is to be noted that during the artificial respiration there were periods when the pulse became palpable and, indeed, on two occasions, artificial respiration was discontinued because spontaneous breathing took place. On both of these occasions, however, the respiration was short lived.

SUMMARY

The present article is offered in order to present the hazards of curarization prior to electroconvulsive therapy. It is felt that an insufficiency of such reports in the literature tends to make physicians utilizing electroconvulsive therapy less cautious than is warranted with so hazardous a drug as curare. Furthermore, we know too little about the personal sensitivity of patients to this drug. In the case in hand, the patient had tolerated curarization, utilizing the same or greater amounts of curare on five previous occasions without untoward effects. There was no strong indication of the patient's intolerance to curare. Possibly this patient had a subclinical form of myasthenia gravis as described by Riggs and Schlomer.¹ Perhaps other factors were at play, but these could not be adequately determined before the fatal accident.

Council on Foods and Nutrition

This paper was prepared at the request of the Council and is one of a series appearing in THE JOURNAL. Later the entire series will appear in book form as the Council's Handbook of Nutrition.

JAMES R. WILSON, M.D., Secretary.

PROTEINS IN NUTRITION

HOWARD B. LEWIS, Ph.D.
Ann Arbor, Mich.

The term protein was suggested by the Dutch chemist Mulder in 1839 as a designation for the universal component of tissues, both plant and animal. Protein was characterized by him as "unquestionably the most important of all known substances in the organic kingdom. Without it no life appears possible on our planet. Through it means the chief phenomena of life are produced."¹ Today, more than a century after Mulder, the proteins are still "first" (Greek, *prōteios*) in the regulation of vital processes, and disturbances in their metabolism are associated with nutritive failure and with many pathologic conditions with which the physician is confronted.

Proteins are normal constituents of all animal cells and body fluids with the exception of the bile and the urine. They are essential components of both the protoplasm and the nucleus of the cell; hence they exert a profound influence on growth. They are important in the regulation of osmotic relations between cells and intercellular fluids and between tissues and blood and play a significant role in the fluid balance of the body. Many of the best characterized enzymes have been obtained in crystalline form and have the properties of proteins (the "protein enzymes").² A considerable number of the hormones, chemical regulators of the body, either are proteins (the so-called protein hormones)³ or are derivatives of proteins. Many of the substances associated with immunologic and antigenic reactions and similar phenomena are known to be proteins. In recent years the causative agents of certain virus diseases (notably the tobacco mosaic and the bushy stunt of the tomato) have been obtained in crystalline form and exhibit the characteristic properties of nucleoproteins; yet when inoculated into the proper host they multiply and give rise to the specific pathologic changes associated with the virus.⁴ Bacteriophage, a filtrable agent with the properties of a virus, is also believed to be a nucleoprotein. Finally, a nucleoprotein is the major constituent of cell nuclei and is believed to constitute the chromatin of the nucleus and thus to form the principal component of the chromosome.⁵

It is notable that proteins exist as large molecules or, possibly, aggregates of molecules. In table 1 are pre-

sented the estimated molecular weights of a few important proteins. It should be pointed out that in the determination of the molecular weights of proteins, many difficult problems arise and that the values obtained by the various methods do not check exactly. The values presented will, it is believed, afford some approximation of the probable size of protein molecules. The large molecules of even the simpler proteins may be compared with those of some other important constituents of tissues or body fluids: sodium chloride, 58; urea, 60; ascorbic acid, 176; dextrose, 180; lactose, 342; carotene (provitamin A), 537, and glyceryl tristearate (a typical fat), 891.

When this large protein molecule is broken down by the addition of the elements of water (hydrolysis), a considerable number of much simpler units, or building stones, are formed, whose molecular weights range from 75 (aminoacetic acid, known also as glycocoll or glycine) to 240 (cystine). These units have the structure and properties of ampholytes (dissociation, so that they may function either as an acid or as a base depending on the p_H of the environment) and are known as α -amino

TABLE 1.—Sources and Approximate Molecular Weights of Proteins

Protein	Source	Estimated Molecular Weight
Insulin	Pancreas	35,000 or 46,000
Pepsin	Gastric juice	35,200
Benze-Jones protein	Urine	35,200
β -Lactoglobulin	Milk	42,000
Ovalbumin	Hen's egg	43,000
Zein	Corn	50,000
Hemoglobin	Human blood	70,000
Serum albumin	Human blood	70,000
γ -Globulin	Human blood	150,000
Urease	Jack bean	422,000
Thyroglobulin	Thyroid	650,000
Antipneumococcus serum globulin	Horse blood	845,000
Bushy stunt virus	Tomato plant	7,600,000
Tobacco mosaic virus	Tobacco plant	40,000,000

acids. From the chemical standpoint, they are characterized by the presence of a carboxyl (COOH) group with acidic properties and an amino (NH_2) group with basic properties, the two groups being attached to the same carbon atom.

The character of the remainder of the amino acid molecule (designated by R, fig. 1) varies, but all the typical products of hydrolysis have in common the presence of the carboxyl and amino groups. Important chemical groupings in various amino acids are sulfur (cystine and methionine), hydroxyl (threonine and serine), benzene nucleus (phenylalanine and tyrosine), guanidine nucleus (arginine), indolyl ring (tryptophan) and imidazolyl ring (histidine).

Fig. 1.—Structure of an amino acid.

Certain units or amino acids present in the protein molecule are considered of especial importance in the structure of tissue (growth) and are commonly designated as the essential amino acids. The chemical nature of these essential units will be discussed subsequently. The formulas of the other amino acids may be obtained from any of the numerous standard textbooks on biologic chemistry.

The amino acids are joined to each other in the protein molecule by a linkage known as the peptide linkage, in which the basic (amino) group of one acid is linked to the acidic (carboxyl) group of the adjacent acid.

with the loss of a molecule of water. A compound made up of two acids thus joined is known as a dipeptide (fig. 2), and a similar compound which contains several (usually an unknown number) amino acids bound together in the peptide linkage is known as a polypeptide.

Hydrolysis of the dipeptide for which the formula is given would break the peptide linkage ($-\text{NH}-\text{CO}-$), and the component amino acids would be obtained. While the peptide linkage may not be the only linkage between the amino acids of the protein molecule, it is certainly by far the most important one. This is borne out by the chemical properties of native proteins (proteins as they are found in nature as contrasted with derivatives formed by the action of heat, alcohol, water, salts, enzymes and the like). The biologic reactions of the proteins are also more closely related to those of amino acids than to those of any other type of hydrolytic product of protein, such as proteoses or peptones.

Just like the amino acids, which are ampholytes and may react with either acids or bases, depending on the

Fig. 2.—Structure of a dipeptide.

of their environment, the proteins as complexes of amino acids (polypeptides) may combine with either acids or bases. For the most part, the proteins as they exist in fluids and tissues of the animal organism function as acids (play the role of anions) and are in combination with bases (cations). Thus, the protein hemoglobin of the erythrocytes is combined in the cell with base (chiefly potassium) as a salt; similarly, milk contains various salts of casein, of which calcium caseinate is important.

When two amino acids are joined in peptide linkage, two different peptides may be obtained; with three amino acids, six peptides, and with five amino acids, 120 peptides. These are known as isomers, since they are all made up of the same units and have the same percentage composition. They differ, however, in the arrangement of the amino acids in the peptide chain (for instance, in the case of a tripeptide, a-b-c, a-c-b, b-a-c, b-c-a, c-a-b and c-b-a, when a, b and c are three different amino acids). Since more than twenty amino acids are known to be of general occurrence in the protein molecule, it is obvious that the possible number of isomeric proteins (polypeptides) is very large. A peptide made up of twenty amino acids, most commonly obtained in the hydrolysis of protein,⁷ each acid occurring once only in the chain, would have a molecular weight of about 2,700. A simple calculation shows that the number of possible isomers of this peptide would be 2,432,902,008,176,640,000, a number beyond the range of human thought.⁸ Each of these peptides would have the same percentage composition, would yield the same amino acids on hydrolysis in the same proportions and would have similar properties. Each would differ from the other in some slight variation in the arrangement of the component amino acids of the peptide chain. Each would, therefore, be a chemical individual distinct from the other isomeric peptides.

If it is remembered that the protein molecule is much larger than the peptide just discussed, that native proteins vary greatly in the amounts of amino acids which they yield on hydrolysis and that some linkages other than the simple peptide linkage almost certainly occur in the protein molecule, it is evident that the possible number of different proteins as they exist in nature is almost infinite. This individuality of natural proteins finds expression in the so-called specificity of the proteins. This may be most simply defined by the statement that every species tends to construct within the organism a protein characteristic of that species. Thus, casein of cow's milk is believed to differ from casein of goat's milk, protein of beef muscle to differ from protein of pork muscle and serum protein of human blood to be different from serum protein of beef blood. While in my opinion the basis of this specificity is undoubtedly chemical and is related to the possibilities of isomerism just discussed, this cannot be proved at present. The specificity of proteins of different biologic origin must for the present be demonstrated by biologic reactions, by the reactions observed when "foreign" protein is introduced into the organism. The phenomena of anaphylaxis, of antibody formation, of food allergies and of many other antigenic and immunologic reactions are all manifestations of this biologic specificity of the proteins, so important in many considerations of medical practice.

The protein of the human diet is obtained from both animal and vegetable sources. Among foodstuffs of animal origin, meats (both muscular and glandular tissues), fish, eggs, milk and milk products are most important. Vegetable protein is most readily available in the cereal grains (wheat, corn, rice, rye and barley), the seeds of legumes (peas and various kinds of beans) and many nuts, of which the peanut is perhaps most important in the human diet. It is estimated that the cereals contribute about 25 per cent of the total calories of the diet of the American people.

The proteins of the foodstuffs, large molecules with colloidal properties, do not diffuse readily through biologic membranes. If these dietary proteins are to be utilized, it is necessary that they be altered so that passage through the mucous membrane of the intestine is possible. This is accomplished in the gastrointestinal canal by the process of digestion, by the action of a group of biologic catalysts or enzymes, whose activities are so coordinated as to effect a rapid and complete hydrolysis to the soluble diffusible amino acids. Since biologically the amino acids are nonspecific, digestion results in the loss of the biologic specificity of the proteins; if this were not the case, large amounts of "foreign" protein would normally enter the blood stream from the alimentary canal and food allergies of protein origin would be of frequent occurrence.

The enzymes concerned in this process are pepsin and rennin of the gastric juice, trypsin and chymotrypsin of the pancreatic juice and a group of enzymes known as peptidases, which are present in the pancreatic and intestinal juices and hydrolyze the peptides. (It should be noted that commercial "trypsin" and the trypsin referred to in the older literature are mixtures of the proteolytic enzymes of pancreatic tissue and include not only trypsin but also chymotrypsin and peptidases.⁹) Digestion is best effected if these enzymes act on the proteins of the diet in the natural anatomic sequence, i.e., gastric, pancreatic and intestinal.

7. Two amino acids commonly listed in textbooks of biochemistry are not now accepted as units of the protein molecule, i. e., hydroxyglutamic acid and norleucine.

9. Northrop,² pp. 62-63.

Digestion proceeds rapidly in the intestine; the amino acids are absorbed as rapidly as they are formed by the activity of the enzymes. Although digestion studies in vivo with experimental animals with fistulas at various levels throughout the alimentary canal have clearly demonstrated that the major portion of the ingested protein is completely hydrolyzed to amino acids, or at least to very simple peptides,¹⁰ the question of the absorption of some portion of the protein of the diet in unaltered form into the circulation must be considered. Early workers whose experimental methods were not adequate were led to favor the possibility of such an absorption in unusual circumstances, particularly in young animals, in which the intestinal membrane was assumed to be more readily permeable. The use of the newer methods of immunology, by which accurate detection and differentiation of very small amounts of specific proteins have been made possible, has thrown new light on the question. By these methods it now appears to have been demonstrated that in many persons, without regard to age or sex, a detectable amount of certain proteins frequently enters the blood stream in an unaltered state via the alimentary canal. As Walzer¹¹ has expressed it, "The regularity with which the phenomenon occurs in the average individual and the uniformity of results when repeatedly tried under identical conditions on the same subject, preclude the possibility that this is an accidental or unusual occurrence." Of the protein foods studied, the most extensive observations have been reported with egg white.¹² These observations are of special significance in relation to the phenomena of sensitization to specific protein foods. However, it should be remembered that the methods of immunology are capable of detecting exceedingly minute amounts of protein and that the total amount of protein absorbed thus unaltered must be slight. One may, then, with a reasonable degree of confidence look to the behavior of the individual amino acids for the interpretation of the role of protein in normal nutrition.

The products of the digestion of proteins, chiefly the amino acids, enter the portal blood on absorption from the intestine and are distributed to the tissues by the systemic blood. The postabsorptive increase in the amino acid nitrogen of the blood, although not large, is unquestioned. The amino acids are rapidly taken up by the tissues, and the amino acid content of the blood returns to normal.¹³

One of three fates awaits the amino acids which thus enter the cell. The first is condensation with other amino acids, selected by the particular tissue in question from the pabulum supplied to it by the blood, to form the protein characteristic of that particular tissue or cell. This specific synthesis, the converse of digestion, makes possible the maintenance of the individuality of the cell. This process acquires a particular significance in young animals in which building of new tissues.

growth, must occur for normal development and in the adult in normal pregnancy and lactation.

A second metabolic path is utilization of the amino acids for some special purpose in the animal economy apart from the general synthesis of cellular protein. Examples of this are the synthesis of such proteins as hemoglobin, fibrinogen and the serum proteins. Amino acids are utilized also for the formation of specific proteins with hormonal function (insulin and prolactin) or amino acid derivatives which are hormones (epinephrine and thyroxine) or chemical regulators which are not usually classed as hormones (glutathione, histamine and creatine). The synthesis of the "protein enzymes" (pepsin, trypsin, catalase and carbonic anhydrase) also occurs. The details of the reactions which lead to the synthesis of such specialized proteins and protein derivatives are not as yet clearly understood.

After the needs of the cells for these two purposes have been met, an excess of amino acids may still remain in the cells. The fate of this amino acid fraction is deamination—removal of the nitrogenous portion of the molecule—and utilization of the non-nitrogenous portion, since, in contrast to fat and carbohydrate, storage of protein or amino acids for any considerable time does not appear to be possible. The nitrogenous fraction of the molecule, split off as ammonia, is rapidly converted into urea under normal conditions and is eliminated in this form by the kidneys. The efficiency of this transformation is demonstrated by the fact that normally systemic blood contains less than 0.1 mg. of ammonia nitrogen per hundred cubic centimeters, while the urea content of normal blood calculated as urea nitrogen is approximately 17 mg. per hundred cubic centimeters. The non-nitrogenous residue which remains after deamination may either be transformed into dextrose and used in this form, the antiketogenic fraction of the protein molecule, or be converted to fatty acids, the ketogenic fraction of the protein molecule. Whether the non-nitrogenous residue is converted to dextrose for utilization in that form depends on the chemical structure of the original amino acid. In general, one may say that about half of the amino acids present in the molecule of any individual protein may give rise to dextrose in intermediary metabolism.

Physiologic and nutritional studies alike have emphasized the role of the amino acids as structural elements, the building stones of living protoplasm. What are the amino acid requirements for the construction of new cells? Are all the amino acids of equal importance in nutrition? These questions have been answered in part by the studies of Rose, which were based on the pioneer work of Hopkins and of Osborne and Mendel. It should be emphasized that the discussion immediately following concerns the requirements for growth of one species, the white rat. Rose¹⁴ first demonstrated that it was possible to obtain normal growth of young white rats when the protein element of the diet was supplied by a mixture of chemically pure amino acids, which included those acids known to be of general occurrence in the protein molecule. The effect of the removal of the various individual amino acids from this mixture was then studied. The absence of certain acids from the diet resulted in impaired growth or in some cases considerable losses in weight and ultimately death. These amino acids, designated

enous equilibrium is again obtained, but at a higher level of excretion. If new protein is being synthesized in the body (growth, pregnancy and lactation), the nitrogen excreted is less than that of the diet and the subject is said to be in positive nitrogen balance. When the nitrogen excreted is greater than the dietary nitrogen, a condition of negative balance is obtained. This indicates an inadequate intake of dietary protein or an excessive breakdown of body protein associated with disease.

The level of endogenous nitrogen protein metabolism may be obtained by a consideration of the nitrogen excretion of an adult maintained on a diet high in its content of fat and carbohydrate but containing no protein. Experimentally this has been observed to approximate 3 Gm. a day for a man weighing 70 Kg., or about 20 Gm. of protein.³⁸ There is, however, evidence that to provide a safe allowance for health, protein in excess of the requirements for maintenance is essential. It is argued that excessive consumption of protein imposes a burden on the organism and is likely to be harmful. The proponents of the high protein diet, on the other hand, argue that a surplus of protein may have a beneficial effect on health and well-being and cite studies of racial groups which indicate that physical efficiency and health can be related directly to the intake of protein and particularly of animal protein. The high protein diet of the Eskimo, in which the protein is obtained almost entirely from meat, does not appear to have resulted in a high incidence of renal disease in this group.³⁹ The carefully made studies of the metabolism of two Arctic explorers who lived for a year in the temperate zone on a diet of meat only are of particular interest. It must be remembered, however, that in studies of human populations the protein element is only one of many factors in health and that it is difficult to assess the role of dietary protein alone without many greatly extended studies.⁴⁰

Outstanding among the pathologic conditions which have been associated with prolonged ingestion of a diet inadequate in its protein content is nutritional edema (known also as war or starvation edema), which has been observed clinically in Europe, in the Orient and in the United States and can be produced experimentally in animals maintained on a low protein diet.⁴¹ The continued ingestion of the low protein diet results in low levels of plasma protein (particularly the albumin fraction), and the resultant lowering of the "effective" osmotic pressure of the plasma is believed to be one of the causes of the edema.

This discussion indicates the desirability of caution in the selection of a standard protein level for national nutrition. It is not necessary to enter into the details of the controversy between the advocates of the low and high protein diet, a controversy which is excellently and impartially presented in the classic text of Lusk.⁴² Sherman, after a careful consideration of the acceptable balance experiments with human beings, in which nitro-

gen equilibrium was established at low levels of dietary protein, concluded that "a standard allowance of 1 Gm. of protein per kilo of body weight per day appears, therefore, to provide a margin of safety of 50 to 100 per cent as far as requirements of adult maintenance are concerned."⁴³ This standard for adult maintenance has been accepted almost universally, while the need for larger amounts of protein in diets of growing children and of pregnant and lactating women is clearly recognized. The recently adopted standards for national nutrition, as proposed by the Food and Nutrition Board of the National Research Council, provide for 70 Gm. of protein a day in the diet of a man weighing 70 Kg. and 60 Gm. of dietary protein for a woman weighing 56 Kg.⁴⁴

Estimates of the increased requirements for protein during pregnancy and lactation vary greatly.⁴⁵ The protein requirement per kilogram of body weight is high in infancy and decreases as growth occurs until after puberty, when the adult requirements only are necessary. The desirable amount of dietary protein is estimated to vary from 4 Gm. per kilogram a day at 1 to 3 years to 2 Gm. at 17 to 18 years.⁴¹ The necessity of proteins of milk, during the period of active growth can hardly be overemphasized. That increased muscular activity necessitates a larger intake of protein is as yet unproved. Traditionally the diet of highly trained athletes and of laborers engaged in hard work, whose calorific requirements are high, contains much meat and supplies large amounts of proteins.⁴⁶

An increased destruction of tissue protein has long been recognized in a variety of infectious diseases. More recently, loss of nitrogen, as evidenced by decided negative balances, has been observed in patients undergoing surgical treatment (notably after fractures) and in patients with severe burns.⁴⁷ In an attempt to make good this loss of protein from the body, a loss which may continue for some days, high protein diets have been recommended, which supply quantities of protein far in excess of those of the "recommended dietary allowances" of the Food and Nutrition Board.⁴⁴ The cause of this increased destruction of protein is not yet understood.⁴⁷

The preceding discussion has been concerned with the quantitative aspects of the protein requirements of human beings. That the dietary protein will be derived from a wide variety of foodstuffs of both animal and vegetable origin is assumed. In the United States, it is estimated that animal protein makes up at least 50 per cent of the protein of the usual diet. If the variety of foodstuffs is limited, care must be exercised in the selection of protein. The chief consideration in the choice of protein must be the furnishing of the essential amino acids to be made available to the tissues by digestion. Since the optimal mixture of the essential amino acids for the nutrition of human beings is not yet known, the diet must supply all the known essential amino acids in liberal amounts. Animal proteins usually have a greater biologic value than do the proteins of vegetable origin. Thus zein, one of the proteins of

the maize kernel, contains no lysine or tryptophan, two important essential amino acids. When the diet is derived exclusively from plant materials, more protein must be eaten. A notable exception is gelatin. This protein, a product of food technology and derived from collagen, completely lacks at least two essential amino acids, valine and tryptophan, and contains little tyrosine and cystine, amino acids which, while not essential, may be important in nutrition. Gelatin supplies a mixture of amino acids, which is inadequate if used as the sole or chief source of these tissue-building stones. The recent claims for the superior food value of gelatin require further and more careful study.⁴⁸ The excellent quality of the mixture of proteins present in milk is notable.

Carbohydrates spare body protein. The breakdown of body protein is significantly increased if the supply of the energy-producing foods and particularly of carbohydrates is not ample. The consideration of the total calorific value of the diet is of special importance when the diet is low in its protein content, as are certain diets prescribed for therapeutic purposes. Diets of high calorific content usually contain liberal or large amounts of protein.

It is known that in the case of certain essential elements present in food (notably the vitamins) the nutritive value may be influenced by preservation, processing and cooking. Thus the nutritive values of a natural foodstuff as determined by chemical analysis may not be a safe guide to its value when prepared for consumption. Since foodstuffs which are important sources of protein are seldom consumed in the raw state, possible changes due to heat must be considered. Even milk in present day practice is usually subjected to the mild heat of pasteurization. The evidence in the case of proteins is conflicting. The biologic value of the protein of certain legumes is believed to be increased by cooking, while the nutritive value of some other proteins (meat, casein and milk products) appears to be lowered by heat.⁴⁹ A detailed discussion is not possible here. Whether such changes are sufficiently extensive to be of practical significance remains to be determined.

No discussion of recent developments in protein metabolism can neglect the mention of the experiments of Schoenheimer in which isotopic nitrogen (N^{15}) has been used as a marker.⁵⁰ These experiments indicate that a "rapid and continuous chemical regeneration of the cell proteins is a general characteristic of living matter," but, despite this striking and continuous chemical activity of the organ proteins, it is believed that these processes "lead to no final quantitative or qualitative changes" in the composition of the tissues.⁵¹ This is in confirmation of the older belief in the constancy of composition of the structural elements of protoplasm. While the observations of Schoenheimer and his group are of great physiologic significance, it is not believed that at present they suggest any changes in the current practices of dietetics so far as concerns protein.

In an earlier discussion (1942) of protein in nutrition, I quoted Karl Thomas (1929), with reference to the chief unsolved problems of the role of proteins in nutrition. No better conclusion to this presentation of the problems of 1948 can be given than to reiterate the statements of Thomas.⁵² "What we need to know is: 1. Which amino acids must be present in the food, 2. How much we require of each, 3. And to what purpose." Today, after more than a decade of intense interest and research in protein metabolism, these questions still epitomize the problem of the role of proteins in nutrition. When they can be answered exactly, the role of protein in the diet will be known and one will be able to determine the dietary value of every mixture of proteins in natural foodstuffs. Until this knowledge is obtained, one may rest assured that for the healthy person, natural protein chosen from a wide variety of foodstuffs and supplied in ample amounts is the practical solution of the problem of dietary protein. The body may be able to synthesize the nonessential amino acids from the essential ones, but there is no knowledge that the imposition of this task on the cells represents physiologic economy. Living organisms have synthesized a wide variety of proteins containing both essential and nonessential amino acids; surely one cannot do better at present than to insure such a supply of amino acids as mixed proteins afford. The gastronomic urge will prompt one to eat meat, eggs and other protein foodstuffs in preference to unappetizing protein hydrolysates or mixtures of pure amino acids.

SUMMARY

Proteins are large complex molecules with colloidal properties and function as ampholytes, i.e., may dissociate, either as acids or bases. The structural units of the protein molecule are α -amino acids, of which some nineteen are clearly recognized as components of the usual types of proteins.

Proteins are almost completely digested to the amino acids in the gastrointestinal canal; the amino acids are absorbed into the portal blood and circulate in the systemic blood, from which they are rapidly removed and stored for use by the cells of the various tissues.

The amino acids, thus made available from the diet, may be used for the various synthetic reactions, formation of proteins and of essential products derived from amino acids (e.g., thyroxine, epinephrine). The amino acids not required for synthesis are deaminized with oxidation to yield ammonia and α -keto acids. The ammonia is converted to urea and excreted by the kidneys.

Certain amino acids, designated as essential, cannot be synthesized by the mammalian organism and must be supplied by the diet. The other, nonessential, amino acids can be synthesized by the body.

Both animal and vegetable foodstuffs are good sources of protein, provided that they supply adequate amounts of the essential amino acids. In the usual American dietary, the amounts of protein derived from animal (meats, fish, milk and milk products, eggs) and vegetable (cereals, legumes, nuts) sources are about equal.

The minimal recommended protein of the diet for an adult man (70 Kg.) is 70 Gm., or 1 Gm. per kilogram of body weight, and for an adult woman 60 Gm. The required amounts of dietary proteins are increased by pregnancy and lactation. The requirements of the growing child are greatly in excess of those of the adult (e.g., 2 to 4 Gm. per kilogram of body weight per day).

THE HAZARDS OF X-RAY

Medical science advances rapidly. New discoveries are announced frequently. This makes the physician's responsibility heavier and heavier. He has to know the old science and the new also. He has to know the power and the hazards of new devices and must use good judgment in balancing probable good against possible harm.

Think of radiation! The engineers and the nuclear physicists keep developing new apparatus. New researches, including some by the health physicists and biologists connected with the development of the atom bomb, have taught us more about the hazards of the old apparatus, also, such as x-ray and radium.

Even small quantities of roentgen or radium rays can prove damaging. Radiation injury to the skin sometimes leads to cancer, coming even many years after. Some of these patients did not show immediate injury, even so much as redness of the skin. Repeated or continuous irradiation of the whole body can produce aplastic anemia, sometimes leukemia, even when the individual doses have been moderate.

Roentgen rays for diagnosis (films and fluoroscopy) are safe only because radiologists have a long tradition of being careful and because films and screens are so sensitive as to require rather small exposures. Examples of accidental erythema or redness continue to appear, and even of disastrous roentgen ulceration. Many of these come from fluoroscopy for bone setting and for removing foreign bodies. The hazard seems higher among surgeons and general practitioners than among x-ray specialists. Paradoxically, the smaller types of x-ray machines have provided most of the worst cases. Every radiologist has a collection of anecdotes to show how dangerous roentgen rays can be in the hands of those not specially trained.

In treating cancer big doses of radiation are used. Resulting damage to skin and normal structures is severe and obvious. Blistering is often only the proof that a thoughtful and conscientious therapist has given enough radiation to have a chance to cure. Such

damage, including the possibility of late roentgen ulceration, or late roentgen cancer, is not too high a price to pay for cure of a cancer; regrettable, but at present necessary. Perhaps new medical discoveries regarding cancer will outmode the present radiation therapy.

Until then physicians will continue to apply radiation. Patients will bear the accompanying damage. Radiologists must continually test and retest their judgment to see that it is dependable in applying such doses, and they must measure and remeasure the critical quantities of roentgen rays that are applied.

When benign conditions, not cancer and not lethal, are concerned the point of view is different. The situation is not desperate. If the disease does not threaten life, treatment that may do harm should be avoided, or treatment that may lead to trouble later in life. Are radiologists too light hearted in advising a few hundred roentgens for subacromial bursitis? What degree of desperation should be demanded in this painful condition before inflicting the (rather mild) roentgen injury incidental to 300 r? And if not relieved, how many times shall the damage be compounded by repeated dosage? There is no "official" answer to this or to similar pointed questions in the therapy of acute and chronic arthritis. Such a dose may in fact be thoughtfully accepted in many a case, but in every instance it ought assuredly to be thoughtful and not "routine."

In cases of postoperative parotitis or of gas gangrene, such moderate doses are given more boldly, even though one is less sure of their effectiveness, for the acute danger of the disease is apparent.

In dermatitis, especially allergic dermatitis, roentgen radiation is often an almost magical palliative. Recurrences are common. Treating the recurrence increases the total irradiation. After many recurrences the total mounts to the danger limit, but one also foresees that the patient will have been well persuaded by the many temporary successes that roentgen irradiation is the treatment he needs. His demand for another treatment may be well nigh undeniable. Foresight therefore warns that one should not use roentgen rays in dermatitis until literally everything else has been tried most patiently.

Many babies have red birthmarks, hemangiomas, typically "strawberry marks." These often respond well to roentgen rays or radium. Heavy doses have been followed in some by equally unsightly scars or telangiectases. A few have resulted in arrest of epiphyseal growth and a deformed limb. There are reports that nearly all strawberry marks disappear spontaneously by the age of 5 years. In the face of this, a radiologist needs to be sure indeed that his irradiation is such as will do little damage to the skin and no damage to the bones.

Common warts are distressing to fastidious persons and on the sole of the foot can be crippling. Topical, surgical and medicinal treatments are often disappointing. Radiologists rather generally accede to a request to treat them, and many times succeed. Doses advised are not small in amount, and are tolerable at all only because small in area. Nevertheless, there are many instances of ulcers following roentgen irradiation even by trained radiologists. Perhaps it is too soon to condemn such therapy, but at least the treatment should not be undertaken lightly. One should be certain of the dose and area. Careless history taking or slovenly records can result in repeated irradiation of the same area. This can be disastrous, even if the interval between treatments has been long.

In attempts to stem the discouraging tide of hardness of hearing great enthusiasm has developed for radium irradiation of the mouth of the eustachian tube. This is being applied to children under the supposition that much adult deafness arises from years of interference with aeration of the tympanum. How good the statistical evidence is of this etiology of adult deafness is not yet established. One has no doubt of the effectiveness of irradiation in shrinking the hypertrophied lymphoid tissue. The real question, not yet answered, is how much late damage may develop from these irradiations. Although the total dose in milligram-hours seems small (1 per cent of what is often used in uterine cancer), yet the local tissue dose is not small, for the radium is only 1 or 2 mm. from the mucous membrane. Otolaryngologists might be inclined to feel that all they have to do is to buy or rent the proper radium applicator. The real difficulty is in judging whether or when such a damaging therapy is justified.

A therapeutic irradiation that has long been viewed askance by many radiologists is its use for epilation to cure ringworm of the scalp in children. In the early days when equipment was unreliable and measuring instruments unsatisfactory, alopecia was a frequent sequel. Today many radiologists and many dermatologists who do have adequate equipment nevertheless refuse to do therapeutic epilations. They feel that the chances that permanent alopecia will result are not negligible and that the blame for such an accident is beyond their willingness to face. This attitude seems less than worthy of our profession. If any patients with ringworm of the scalp need irradiation, then duty demands that one do it if technically equipped, or if not so equipped that one know whither to refer the patient to get it done.

Most cases of tinea capitis can be cleared quickly or slowly by local treatment with proper medicaments (iodine, fatty acids, etc). Some, especially *Microsporon audouinii*, will not clear and would persist until puberty so alters the sebum as to make the soil no longer suitable for the organism. Epilation, however,

results almost always in cure. Pulling the hairs by hand is so tedious as to be impractical. Roentgen epilation is practical and has been demonstrated to be safe, provided the technic is painstakingly correct. Even so, a perfectly even effect over the whole scalp seems almost impossible to attain. The dosage must be precise. Some careful radiologists measure the output of the tube immediately before every epilation treatment. When such care is taken alopecia rarely follows.

A conscientious radiologist might well equip himself to offer this service. He would undertake it in close consultation with the practitioner, with the help of a dermatologist if necessary. Considering recent advances in the topical (ointment) treatment of tinea capitis, he would insist that modern methods first be persistently and carefully applied under competent control for three months. He ought to have cultural proof that the infection is in fact *M. audouinii*, that he is not dealing with mere reinfections from a mangy dog or cat. So safeguarded, one could conclude that a patient would be well advised to risk the tiny chance of alopecia in order to escape the overwhelming probability of persisting scalp infection throughout all the remaining years to puberty.

Roentgen treatment for benign conditions should be used only with a vivid appreciation of its capacity for harm and with an overt evaluation of its presumptive benefits weighed against the known and possible injuries inseparable from its use in effective dosage.

IN TIME OF PEACE

If current efforts at world organization for peace fail, military leaders warn that the next war will not be a declared war but might start with bombing or other attack on our large cities; overnight, they say, we may find ourselves with enormous refugee populations maimed, homeless and confused; industrial populations and rural populations may be attacked just as directly by means of new technics. Confusion will be "twice confounded" unless the medical and allied professions have somehow managed, through a process of preplanning and preexamination, to provide for the prior identification and physical fitness classification of every citizen for military or civilian duties in an all-out response of the entire population.

Accepting these warnings of military leaders at their face value, the medical and allied professions must organize still further to meet the nation's need. The following important services will be required in the months immediately ahead; first, developing a system for classifying all persons according to their physical fitness for military duty and for civilian duty; second, examination and classification of the population of cities of 100,000 and over; third, extension of these efforts

to the remainder of the population as rapidly as practicable, and, fourth, among other measures not directly medical in nature, assisting in developing a system for rapid personal identification.

The task will require the combined efforts of the medical and allied professions over months and perhaps years. The beginning of a rough but apparently usable system of classification is already available in the Physical Profile Serial used by the British and Canadian Armies in World War II and developed further and applied by our armed forces. The modification of this classification system to meet the needs of all civilian as well as military groups would not appear to be a too difficult task.

If the proper government authorities will make it plain as to what is actually needed, the medical profession will do its part. Though the leadership under current organization must come from other than the Defense Establishment, all efforts must be integrated with the military plans. Through the official bodies created by the House of Delegates and the Board of Trustees the American Medical Association can act promptly and efficiently.

Current Comment

INTERRELATIONS OF CANCER AND ARTERIOSCLEROSIS

Cancer and arteriosclerosis together account for about one half of all deaths. An examination of the general characteristics and of the factors contributing to the development of the two diseases yields evidence suggesting the possible existence of certain connections between them. Cancer as well as arteriosclerosis affects most often persons of middle or advanced age. Thus, a long preparatory or latent period seems to precede the manifestation of both conditions. Clinical and experimental evidence indicates that tissue anoxia may be involved in the production of cancer as well as of arteriosclerosis. Among the various causative agents known or suspected for both diseases cholesterol and its oxidation products assume a special place. For many years hypercholesterolemia and disturbances of the lipid metabolism associated with diabetes mellitus and hypothyroidism have been related to the development of atherosclerosis. It is known, on the other hand, that endemic nontoxic nodular goiter is the main source of cancer of the thyroid,¹ while recent statistical analyses show that the incidence of cancer is higher in diabetic persons than the expected incidence among people of the general population.² It may not be, therefore, a mere coincidence that certain deficiency states involving the oxytropic and lipotropic factors of the vitamin B

complex are related to disturbances of the lipid metabolism favoring the development of atherosclerosis as well as of cirrhosis of the liver, with subsequent carcinoma of that organ.³ The procarcinogenic action of biotin and fat and the anticarcinogenic effect of riboflavin on the production of hepatocarcinoma of rats given certain aromatic azo dyes furnish additional evidence in this respect. The occurrence of seasonal vitamin B deficiency has been related to the excessive incidence of precancerous and cancerous lesions of the oral and pharyngeal mucosa among the population of Northern Sweden, while the feeding of a diet deficient in choline and pyridoxine has caused in rats the appearance of papillomatous excrescences of the gastric mucosa and of primary cancer of the liver. Dietary ingestion of cholesterol has been used with contradictory results for stimulating in experimental animals the carcinogenic action of tar, crude paraffin oil and ultraviolet rays. Weil-Malherbe and Dickens⁴ observed that the carcinogenic potency of 3,4-benzopyrene injected subcutaneously into mice was accentuated when this agent was dissolved in a 3 per cent solution of cholesterol in tricaprylin, while it was reduced when the chemical was administered in a tricaprylin solution containing 1.5 per cent lecithin. Cholesterol and lecithin seem to display in these experiments the same antagonism that they are known to possess in the development of atherosclerosis. Hieger⁵ recently suggested that cholesterol itself might be a slow carcinogen or might be the carrier of small amounts of a potent carcinogen. Cholesterol seeds have been used for years as carriers of carcinogenic hydrocarbons in experimental work; it may be that this steroid exerts similar affinities and retaining properties for lipid-soluble endogenous or exogenous carcinogens. Photochemical or thermic oxidation products of cholesterol have been related in recent years to the development of actinic cancer of the skin and of "dietary" cancer of the stomach.⁶ Heuper observed in rats exposed to prolonged ultraviolet irradiation not only cancers of the skin, but also extensive arterial calcification. Similarly the development of leukemia and arteriocalcinosis has been observed⁷ in mice fed a diet low in cystine and painted with an ethereal solution of methylcholanthrene. Finally, mention may be made of the not infrequent coexistence of endarteritic changes in the subcutaneous arteries and carcinomatous reactions of the epidermis in chronic radiodermatitis. Although the observations recorded do not permit definite conclusions as to the nature and existence of interrelations between cancer and arteriosclerosis, the evidence presented is sufficient to merit general attention.

ORGANIZATION SECTION

JOINT COMMITTEE FOR THE COORDINATION OF MEDICAL ACTIVITIES

Abstract of Report of Meeting in Chicago, June 5

The meeting of the Joint Committee for the Coordination of Medical Activities was called to order by the Chairman, Dr. Ernest E. Irons, at 9:34 a. m., Saturday, June 5, 1948, in the Board Room of the American Medical Association Building in Chicago. Members and guests present were:

Dr. Donald G. Anderson, (A. M. A. Council on Medical Education and Hospitals)
Brig. Gen. George E. Armstrong (Office of the Surgeon General, U. S. Army)
Dr. Walter L. Bierring (Federation of State Medical Boards)
Mr. George W. Cooley (A. M. A. Council on Medical Service)
Mr. P. H. Costello (American Pharmaceutical Association)
Dr. W. Palmer Dearing (U. S. Public Health Service)
Dr. Warren F. Draper, (American Red Cross)
Capt. William E. Eaton (Office of the Surgeon General, U. S. Navy)
Dr. Lester J. Evans (American Medical Association)
Dr. Robert P. Fischelis (American Pharmaceutical Association)
Dr. Elmer L. Henderson (American Medical Association)
Dr. Ernest B. Howard (American Medical Association)
Dr. Ernest E. Irons (American College of Physicians)
Dr. George F. Lull (American Medical Association)
Capt. Frederick L. McDaniel (Bureau of Medicine and Surgery, U. S. Navy)
Dr. J. J. Moore (American Medical Association)
Dr. H. B. Mulholland (A. M. A. Committee on Rural Medical Service)
Dr. Howard C. Naffziger (American College of Surgeons)
Dr. Carl M. Peterson (A. M. A. Council on Industrial Health)
Col. Paul I. Robinson (Office of the Surgeon General, U. S. Army)
Dr. R. L. Sensenich (American Medical Association)
Dr. E. R. Serles (American Pharmaceutical Association)
Dr. H. H. Shoulders (American Medical Association)
Miss Mary E. Switzer (Federal Security Agency)

APPROVAL OF MINUTES OF MARCH 6 MEETING

The minutes of the meeting held on March 6, 1948, were approved after the Chairman had stated that minor corrections received by mail had been made.

NATIONAL HEALTH ASSEMBLY

Dr. Lull, a member of the Executive Committee of the National Health Assembly, reported as follows:

I am just one of a great number of physicians who attended the Assembly. A list of who was there, by organizations, is now being prepared and will be of interest; for instance, it will be found that the Red Cross had 40 representatives in attendance.

The Assembly went off far better than many of us expected it would. Most of my time and that of my associates was spent in the panel on medical care, which was quite heavily loaded with labor leaders of different types. The conduct of the men in this panel was such as to deserve favorable comment. All those who were representing organized medicine were willing to meet with other groups and discuss the problems; they had no fixed ideas. Since the meeting the labor groups have communicated with the Council on Medical Service and have expressed a desire to meet with representatives of the American Medical Association.

There were several interesting occurrences in the lobby: One was that a representative of a labor group said, "Why should we go out and fight for compulsory health insurance, for which we would have to pay taxes, when the trend is now for the employer to pay for it anyway?" However, that was not the attitude of the labor leaders in the meeting; they were "all out" for this type of health insurance.

The panel on chronic diseases was presided over by Dr. James R. Miller, an A. M. A. Trustee. Several other panels where there was adequate representation of the medical profession went along very quietly. Mr. Ewing said he was not going to be bound by anything; that he was going to report to the President, and that he would draw up the ten year plan the President had requested regardless of what anyone else thought.

A notice was circulated from the *Mid-Month Survey* that the plan would be published this month. Dr. Fishbein contacted Mr. Ewing, who said that when it was released it would be released to all publications at the same time. The Executive Committee is to meet on June 28, after Mr. Ewing has reported to the President. Just what his report will be we do not yet know.

It was Miss Switzer's belief that of all the panels of the Assembly, the one on chronic diseases may have the most influence in devising a plan for the future. Dr. Mulholland thought that in the meetings of the Rural Health Section the farm groups and the doctors got much closer together in trying to solve some of their problems, realizing that each group had something to offer the other. Drs. Bierring and Mulholland

spoke of discussions in the Rural Health Section wherein the farm groups were vociferous in demanding that there be more medical schools, and Dr. Dearing said that the whole group of rural people are worked up about their inability to get as much service as they think they need. It was Dr. Bierring's opinion that the discussions in the Section on Environmental Sanitation were very constructive.

NATIONAL CONFERENCE ON FAMILY LIFE

Miss Switzer presented the following report:

The National Conference on Family Life took place at the end of the week in which the National Health Assembly was held, and it was not possible for me to attend very many of the sessions. No recommendations, as such, came out of the Conference except a plea to work together to improve family life in general. On the whole, the background material sent ahead of time to the participants seemed to please them. Most of the time of the section on medical care was spent in editing the advance material, which, generally, seems to have been found useful by the educational groups. Most of the publicity given the Conference was concerned with the discussions in the section on sterility. The Conference was an experiment. If its proceedings are circulated widely, attention will be focused on certain problems that will give community groups something for which to work. It was well worth while, and nothing radical or revolutionary came out of it; it was a constructive move.

BIPARTISAN COMMITTEE ON REORGANIZATION OF FEDERAL AGENCIES

Dr. Dearing said: The Public Health Service is a sort of "guinea pig" in this connection. Various studies are being farmed out to nongovernment concerns. An outside group is studying the government service as a career, picking out persons in individual jobs and interviewing them. There are two groups within the Bipartisan Committee that are concerning themselves with the branches of the government having to do with medical affairs; one is that of which Mr. Tracy Voorhees is chairman and the other is the Brookings Institution, which is now responsible for studying public health activities. These two groups are working together to some extent. Then there is a task force on field organization; that is, on the relation of the Government to the states. The organization of the Bipartisan Committee is about as complicated as that of the Government itself.

RURAL MEDICAL SERVICE

Dr. Mulholland presented the following report on the activities of the American Medical Association's Committee on Rural Medical Service:

The employment of a field representative for the Committee on Rural Medical Service was recently authorized, and we are now negotiating with a highly qualified person who can be sent out to explore what is being done in the various states. We think this activity will cause the farm people to feel that we really are trying to do something down to the "grass roots" level.

On June 25 the executive committee of the Council on Medical Service and the executive committee of the Committee on Rural Medical Service are to meet with the cooperative health group here in Chicago. This will be the first of a series of exploratory conferences to find a common ground with the health cooperatives. Similar conferences will be held with labor organizations. We propose to have a meeting in the fall with representatives of farm groups and organizations to bring together with those farm groups all of the state chairmen of the Committee on Rural Medical Service. We feel that our February Congress on Rural Health does not draw in enough doctors on the state level.

Our Committee will have an exhibit at the Chicago Session of the American Medical Association this month, which will be a practical demonstration of what has been and is being done in several states to try to solve the problems of medical service in the rural areas.

Dr. Shoulders asked Dr. Mulholland whether he had observed any trend since the war for physicians to go to small towns and rural areas to practice, which was not the case previously; the reply was that there is such a trend and that the secretary of the Committee on Rural Medical Service, had stated that there is no difficulty in getting a doctor to go into a community of 1,000 persons where there are good facilities for practice.

In response to a question by the Chairman whether or not the people in all these small communities actually need a physician, Dr. Mulholland said, "They think they do," and also stated that the Committee on Rural Medical Service is attempting to make an up-to-date compilation of actually needy areas.

Chairman Irons spoke as follows:

I am much impressed with the trend of discussions in this country as illustrated by the reports on the National Health Assembly, the National Conference on Family Life, the Bipartisan Committee, and so on. All of this, it seems to me, is a voluntary attempt on the part of those who have done some thinking on the subject to improve the technic of living together. It has to do with the social motivations which underlie practically everything we do. Divergence of opinion lies not in the desirability of our relations with each other or our methods of doing things but in the methods of cure of the faults we discover. That has been true throughout history. The faults of social living together, the results of invention drawing people together in larger and larger communities and the fact that rising standards of living introduce continually new problems and new things for people to want all are combined in what might be called social motivations, which underlie not only medicine but all social relations. The difficulty is not that we do not recognize the necessity of alleviating social injustice but that we do not agree on the method of cure. What we physicians have in mind is to prevent, if possible, the introduction of methods of cure that have always failed throughout all history. The fact that we freely and openly discuss all these diverse questions here is an encouraging feature of the national thinking.

HOSPITAL SURVEY AND CONSTRUCTION PROGRAM

Dr. Dearing reported as follows:

At present the Hospital Survey and Construction Act provides that if a state has not enacted provisions for establishing and enforcing minimum standards of operation by July 1, 1948, such state will become eligible for further participation in the program. A Bill provides that passage of provisions for enforcement of minimum standards of maintenance and operation, after the July 1, 1948, deadline, will reinstate such state to eligibility for a federal allotment in the Hospital Survey and Construction Program. This bill passed the House on May 18 and was referred to the Senate Committee on Labor and Public Welfare. There has been no further action on it. Only one state is not under the wire.

Four states, Delaware, Nevada, Rhode Island and Wyoming, have not yet submitted state plans.

The number of projects approved and the cost involved are:

	No.	Total Cost	Federal Share
Initial applications approved.....	285	\$131,385,812	\$37,935,201
Complete applications approved....	34	13,610,851	4,039,268
Totals	319	\$144,996,663	\$41,974,469
Distribution of projects by type of facility:			
General hospitals.....			226
Mental hospitals.....			22
Tuberculosis hospitals.....			16
Chronic disease hospitals.....			4
Health centers.....			45
Other (nurses' home, lab., etc.).....			6
Total.....			319

Analysis of approved general hospital projects:

Forty-three per cent of the total number of applications approved represent projects in towns having a population under 2,500. Eighty-two per cent of the total applications approved are for projects in towns under 10,000 population. Ten per cent of the applications approved represent projects of 100 beds or over. The average is approximately 50 beds. Seventy-five per cent of the hospital projects are located in areas designated as "rural" by state agencies. Sixty-three per cent of the approved projects are located in "A" priority areas.

Payments of federal funds:

Roanoke-Chowan General Hospital, Ahoskie, N. C....	\$12,806.30
Suwannee County General Hospital, Live Oak, Fla....	28,275.90
Duval County Hospital, Jacksonville, Fla.....	70,828.01
Jefferson County Health Center, Birmingham, Ala....	156,681.03
Number of Payments—4, totaling.....	\$268,591.24

A UNIFORM PHARMACY PRACTICE ACT

The following progress report was presented by Dr. Serles:

I would first call your attention to a decision in what is referred to as the Sullivan Case, which clearly places the responsibility of the physician and the pharmacist in saying that a label on a pharmaceutical product must definitely state that the product can be sold only on prescription. The physician should bear well in mind that he should not suggest to patients that they may purchase a familiarly named item which clearly calls for a prescription. In attempting to protect the patient, medication is the responsibility of the physician and of the pharmacist who conforms in meeting requirements by not offering for sale any items not covered.

Extensive study is being given to the development of a Uniform Pharmacy Practice Act, and a committee will soon present a draft of a statute which can be formally considered by this group.

I should like to enlist the thinking of this Joint Committee on a situation which seems to be developing throughout the country, part of which seems to be a desire to make drugs more readily available to patients. I refer to the practice of writing full directions on pharmaceutical products. In following such a program, the thought is that it gives a fine advantage to the patient, helping him to procure what he needs. The American Pharmaceutical Association would take the very definite stand that preparations which contain potent drugs certainly could not have a single direction printed for all conditions. That is to say, we all know there is not one set of directions for all uses of a product offered on the market.

The discussion of Dr. Serles' statement was as follows:

DR. FISCHLIS: There appears to be a disposition on the part of the patent medicine industry to take advantage of the position of the Food and Drug Administration in this matter, which is that the Administration

leans over backward in trying to show that it is not using the Food, Drug and Cosmetic Act to discourage self medication but is trying to make self medication safe and, to that extent, is insisting that labels contain certain warnings. That, however, presumes some knowledge of medicine on the part of the patient; of course, the patent medicine industry says: "What the Food and Drug Administration has endorsed is the only thing we are putting on the market."

MISS SWITZER: I believe that the integrity of the Food and Drug Administration has been sufficiently established that it might be possible for it to take a little different attitude, and perhaps it ought to revamp its point of view on this. It might be desirable to give some thought in the discussion of the Uniform Pharmacy Practice Act to how the Administration might be brought in and asked to review the situation. The thinking of the Administration is changing in many ways; they recognize that the pioneer days are past and that the primary problem is not policing.

CAPTAIN EATON: Is anything being done or can anything be done to control the tremendous advertising of aspirin, particularly over the radio?

DOCTOR SERLES: The only control would be a crystallized public opinion. Another enormous class of products needing additional control includes the insecticides, fungicides, etc., that are brought into household use. In every store of a certain chain grocery concern you will find a 10 foot counter with a display of every possible pharmaceutical item it can contain.

DR. FISCHLIS: There is another point on which the stand of the pharmaceutical profession has been misunderstood, and that is the matter of channeling all sales of drugs through the pharmacies. The argument against it is that anybody who can make a label or make change ought to be able to sell drug products, but there is a great difference in having these drugs handled by men who have had education in the administration and use of drugs and men who are only merchandizers. The state under its police power regulates the practice of a pharmacy, but there is no such power with respect to a grocery store.

It was moved, seconded and carried, that the Food and Drug Administration be invited to send a representative to the meetings of the Joint Committee.

AMERICAN RED CROSS BLOOD BANK PROGRAM

Dr. Draper presented the following statement:

The National Blood Program has been progressing very successfully and very smoothly. In addition to the six centers mentioned at the last meeting of this committee three new centers have been opened, one at Tucson, Ariz., one at San Jose and one at Los Angeles, Calif. The program is now serving the blood requirements of six or seven million people, which is not a bad record for the first year. There has been no difficulty whatever in getting all of the blood required in the areas served. There has been no complaint or any criticism at all from any of the national blood centers. The physicians and the hospitals have all expressed themselves as being much pleased. For the first time it has been possible to undertake operations requiring a great deal of blood which the surgeons would not have undertaken if the supply had not been satisfactory.

As you know, prior to the National Blood Program, there was a local program of the Red Cross known as a Permissive Program, which was simply an arrangement whereby the local Red Cross chapter entered into an agreement with the local medical society under which the chapter agreed to recruit donors. Roughly, some 35 communities are operating on this Permissive Program. It is not ideal but has to be kept on until the national program can catch up and absorb it. Criticisms that do occur come from these diverse local programs, and now and then some Red Cross chapter does some unfortunate thing which ought not to have been done. The Red Cross can not apply the iron fist to prevent difficulties from sometimes happening.

The Red Cross approached this matter in the very finest way it could and received the approval, in principle, of the American Medical Association and the approval of other national agencies. It is inconceivable that the program could be defeated now. Furthermore a situation of national emergency may be developing. The Red Cross certainly is not going to give up its program; it would have to go before the public.

The committee which was authorized by the House of Delegates of the American Medical Association to study the Red Cross Blood Bank Program has formulated its report, which was published in THE JOURNAL for May 8, 1948. The Red Cross has accepted everything that the House of Delegates has asked it to accept and has played ball straight down the middle of the fairway.

WORLD MEDICAL ASSOCIATION

The following information was presented by Dr. Irons:

The office of the World Medical Association has been established in the building of the New York Academy of Medicine. A meeting of the Council was held in New York during the last week in April. This meeting was very harmonious, quite different from the one in Paris in 1947 when a rather serious time was had with a communistic element which tried to disrupt the organization. The meeting in New York lasted for three days. An Executive Secretary was elected in the person of Dr. Louis H. Bauer of Hempstead, N. Y., who is a member of the Board of Trustees of the American Medical Association and a past president of the Medical Society of the State of New York and is prominent in many other ways in medical affairs in this country. Dr. Bauer has been persuaded to take over his work temporarily and perhaps, if necessary, will later give it his full time.

A meeting of the full Assembly of the World Medical Association had been planned for September in Prague, but after what happened in Czechoslovakia a while ago it was felt that it would not be wise to meet there. It appeared that representatives of two nations would not be welcome in Czechoslovakia, so the meeting was changed to Geneva, Switzerland, and will take place on September 5, 6 and 7, 1948.

The Council meeting in New York was quite interesting. The member from Czechoslovakia not only brought invitations for the officers and

Council to bring the Assembly to that country but also announced that the government would entertain the Council at some resort for two weeks with all expenses paid. Following the New York meeting, the Council was entertained by a number of universities, visited American Medical Association headquarters in Chicago and spent about a week in Rochester, Minn. The members from foreign countries were presented with Honorary Fellowships in Alpha Omega Alpha while they were in Chicago. The World Medical Association seems to be well on its way.

To back up the World Medical Association the United States Committee has been formed, the funds for which are coming from contributions from the larger medical organizations, the pharmaceutical industry and individuals. Contributions of \$10,000 have been received from several, and there are also \$10.00 contributions from Founder Members. The United States Committee has undertaken to finance the World Medical Association for five years. It is a big undertaking, but it is felt that it can be done with the support of the medical profession and the pharmaceutical industry.

Dr. Henderson said that each nation has two delegates in the General Assembly and that he and Dr. Sensenich will represent the American Medical Association as delegates to the meeting in Geneva. He added that forty-nine different nations were represented at the meeting in Paris last year.

WORLD HEALTH ORGANIZATION

Miss Switzer commented on the World Health Organization (U.N.) which is to have an assembly in Geneva this month—June 1948—saying that it now appears that the United States will send a delegation. The constitution of the World Health Organization stipulates that preferably the head of the delegation shall be the chief health officer of the government, and it now seems certain that Dr. Thomas Parran will fill that place.

CAREER GUIDANCE AND CLASSIFICATION OF ARMY MEDICAL OFFICERS

Following is an abstract of a statement presented by Colonel Robinson:

For the past three or four years the Surgeon General of the Army has been working on improving methods of personnel management in the medical department. The work thus far accomplished can be divided into three general headings: (1) classification methods; (2) career patterns; (3) management control system.

I want to emphasize that career patterns are in existence for every specialty now utilized in the practice of medicine in the Army.

The Army is now fully prepared to determine its requirements by specialty and by qualifications within the specialty for all medical officers. It is expected that within a relatively short time we shall be able to do this for all Corps within the medical department. Both our procurement program and our training program are now geared to the Career Management System. It is being projected into our Reserve Corps. In order that this knowledge may be utilized to prevent wastage of personnel in future emergencies, it is thought that a like classification scheme should be more universally adopted within the profession. This classification system can be readily adapted to the profession as a whole or any designated part of it (for example, any age group). It is thought that this system is the greatest single contribution to efficient utilization of medical personnel, both in peace and in war, that has yet been conceived.

Dr. Dearing stated that the Public Health Service concurs absolutely with Colonel Robinson's final statement and thinks this is the finest job of working out a plan and system that ever has been done; it is completely applicable to the work of the Service, which is taking steps to adopt it as rapidly as possible with some small differences in the major breakdown. He added: The timeliness of this plan in connection with the work that the National Security Resources Board is undertaking is interesting; professional organizations are being asked to consider the problem of compiling and keeping up a roster of physicians in the country according to a uniform classification system which would be agreed to by the profession and the Government, and certainly this plan is made to order for implementing that program.

Miss Switzer asked how soon it could be determined which line of medical practice an officer will undertake and at what point the potentialities are reviewed and decision made that he shall become a specialist. Colonel Robinson's answer was: At present the individual desires of the officer and the fact that he makes good himself prevail; however, our next project is to contrive some plan whereby we can determine by a scientific method the individual's adaptability; it is intended always in this system that the individual's desire shall be the predominant factor.

At a recent meeting in Washington where a Civil Defense plan was discussed it was proposed that the same kind of rating system described by Colonel Robinson might be applied to the

whole medical profession so that the record of each physician would bear his rating number. Dr. Sensenich doubted the practicability of any agency's putting itself in a position to attach a number to a physician in civil life regardless of whether the system might seem useful. The Chairman agreed with Dr. Sensenich.

STATEMENTS FROM LIAISON MEMBERS

Dr. Evans in referring to the discussion on the National Health Assembly stated: I sat through three days of the Rural Health Panel, and I have never heard such fine talks. The progress made over the years has been phenomenal, and most gratifying are the attitudes exhibited, as well as the fact that people seem to think that it will open up and make more free the relationships between the people who are concerned with health.

Dr. Bierring informed the Committee that another specialty board is on the way, to be called the American Board of Preventive Medicine and Public Health Physicians. It is to consist of nine members, three from the American Public Health Association, three from the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association, one from the Southern Medical Association, one from the Canadian Public Health Association, and one from the group of university schools of public health. First steps were taken in February. It is to meet the need of the physicians engaged now and in the future in a full time career in preventive medicine and public health.

Dr. Bierring stated: A matter that still is of considerable concern to licensing bodies is the problem of recognition and licensure of graduates of the two unrecognized medical schools in this country. One, of course, is now out of existence, but its graduates are applying for license in other states. Many of them have completed internships and residencies and some have had military service; perhaps these may be eligible for license. The question is whether these graduates by subsequent study and experience may have acquired sufficient ability to warrant licensing them.

Captain Eaton presented for the Committee's official records a transcript of discussions in a symposium conducted in the Office of the Surgeon General of the Navy in May to which all senior medical officers were called.

Captain McDaniel gave the following report:

The Navy Department has 180 interns, graduates of medical schools since February 1948, who have accepted appointment for Naval internship for the years 1948 and 1949 in Naval hospitals. During the years 1947 and 1948, the Navy had 71 interns in its hospitals.

In addition to this number of interns for Naval hospitals, arrangements are being firming up whereby approximately 100 interns will be placed in civilian institutions. These interns will be members of the Naval Reserve by voluntary enrolment. They will be reserve officers in fact and will receive all pay and allowances of a lieutenant (junior grade) of the Navy, including the \$100 per month additional pay now allowed medical officers in accordance with Public Law 365, 80th Congress.

It should be pointed out that these additional 100 interns will serve in civilian institutions and therefore will not be an additional drain from the civilian institutions.

REPRESENTATION FROM VETERANS ADMINISTRATION AND AMERICAN DENTAL ASSOCIATION

The Chairman brought to the attention of the Committee the fact that no representative from the Veterans Administration or the American Dental Association had been present at Committee meetings for some time. The Committee requested the Chairman to communicate with the Dental Association and the Veterans Administration, emphasizing the desire of the members that there be a renewal of attendance.

REPORT TO HOUSE OF DELEGATES OF AMERICAN MEDICAL ASSOCIATION

It was moved by Dr. Henderson, seconded by Dr. Sensenich, and carried, that the Chairman prepare a report of the past year's activity for presentation to the House of Delegates of the American Medical Association at its meeting in Chicago on June 21 to 25.

NEXT MEETING

The Joint Committee decided to hold its next meeting at American Medical Association headquarters in Chicago at 9:30 a. m., Saturday, Sept. 25, 1948.

The meeting adjourned at 12:50 p. m.

GOVERNMENT SERVICES

ARMY

INSTITUTE FOR PSYCHOTHERAPEUTIC MEDICINE

As part of the Medical Department's program of close cooperation and consultation with civilian doctors, courses in psychotherapeutic medicine were held simultaneously for two weeks beginning September 6 at the Walter Reed General Hospital, Washington, D. C., Letterman General Hospital, San Francisco, and Fitzsimons General Hospital, Denver. Among the ten specialists participating in the course given at the Walter Reed General Hospital were Drs. Thomas A. Loftus, New York; Charlotte Babcock, Chicago; Meyer A. Zeligs, San Francisco; Jacques S. Gottlieb, Iowa City, and Bernard C. Glueck Jr., Ossining, N. Y.

BENEFITS FOR ARMY NURSES

Nurses newly commissioned in the Army Nurse Corps Reserve who have not had prior military experience and who request and accept extended active duty will be given an allowance of \$250 to cover the cost of initial purchase of uniforms. Extended active duty means that the reserve nurse agrees to serve in an Army hospital for not less than one year. Reserve nurses enrolled in the extension courses now available through the Medical Field Service School will earn credit hours for the courses completed, and these hours will count toward eligibility for promotion and retirement. This applies to all reserve nurses regardless of whether or not they have requested and/or accepted

extended active duty. Six complete extension course series are now available for Army Nurse Corps Reserve officers up through the grade of major. Information may be obtained from the Department of Extension Courses, Medical Field Service School, Fort Sam Houston, Texas.

CIVILIAN SPECIALISTS ELIGIBLE FOR RESERVE COMMISSIONS

The Department of the Army announces that civilian specialists in any of seventy-six broadly defined professional and technical specialties may be tendered commissions ranging from second lieutenant to colonel if they apply and qualify. The applicants must be at least 21 years of age and not more than 55. No previous military experience is required. All must be citizens of the United States. In the list of specialties essential to the needs of the Army are, among others, medicine, nursing, nutrition, pharmacy, biochemistry, bacteriology, parasitology, optometry, serology, toxicology and industrial hygiene.

LIBRARIANS WANTED

The Army Medical Library is in need of librarians with medical training or experience, also cataloging experience and foreign language qualifications. For details, write to the Personnel Officer, Army Medical Library, 7th and Independence Avenue, S. W., Washington 25, D. C.

PUBLIC HEALTH SERVICE

NATIONAL ADVISORY HEART COUNCIL

In accordance with the National Heart Act of June 16, 1948, the Surgeon General has appointed the following twelve members of the National Advisory Heart Council:

Dr. Paul D. White, Boston, who will serve as executive chairman of the council.

Dr. C. A. Elvehjem, Madison, Wis., dean of graduate schools, University of Wisconsin.

Dr. Tinsley Harrison, Dallas, Texas, professor of internal medicine, Southwestern Medical College.

Dr. Irvine H. Page, Cleveland, Ohio, director of research, Cleveland Clinic Foundation.

Dr. Burrell O. Raulston, Los Angeles, dean, University of Southern California Medical School.

Dr. T. Duckett Jones, New York, medical director, Helen Hay Whitney Foundation.

Mr. James S. Adams, New York, director, American Cancer Society.

Mr. Maurice Goldblatt, Chicago, president, University of Chicago Cancer Research Foundation.

Mrs. Albert D. Lasker, New York, co-founder, Albert and Mary Lasker Foundation for education and medical research.

Mr. E. B. MacNaughton, Portland, trustee, Good Samaritan Hospital, Portland.

Mr. Ernst Mahler, Neenah, Wis., executive vice president, Kimberly-Clark Corporation.

Mr. Albert J. Wolf, New Orleans, president, board of trustees, Touro Infirmary, New Orleans.

The law requires that six of the members of the council be outstanding experts in the study, diagnosis and treatment of heart diseases. The duties of the council are to advise with the National Heart Institute in developing research programs to help in the attack on cardiovascular diseases; to make recommendations to the Surgeon General on applications of institutions or individuals for research and training grants; to make a worldwide collection of information on research in heart diseases; and to advise on the entire program of the National Heart Institute for controlling cardiovascular diseases. The first meeting of the council was held September 8 at the National Institute of Health, Bethesda, Md.

NATIONAL HOSPITAL FOR TREATMENT OF HANSEN'S DISEASE

The picture is that of the United States Marine Hospital at Carville, La., which is the only institution in the United States devoted exclusively to the care of patients with Hansen's disease (leprosy). This hospital was formerly a Louisiana state hospital but was taken over by the federal government in 1921 and its facilities made available to any citizen of the United States. All building have been replaced by modern fire-resistant structures, and the hospital has a class A rating. There are no charges to patients, and it is the object of the

U. S. Marine Hospital, Carville, La.

Public Health Service which administers this hospital to encourage the greatest liberty to the patient compatible with the accomplishment of the purposes of the hospital. There is a broad field of activities including sports and other recreations for patients, and a monthly publication, *The Star*, published by the patients. The average daily census according to our latest figures was 379. Active treatment is carried on with the newer drugs. During 1946, 43 patients were discharged from this hospital.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

COLORADO

Postgraduate Courses.—A postgraduate course in public health and preventive medicine, to be sponsored by the Colorado State Medical Society, the University of Colorado School of Medicine, the Colorado State Department of Public Health and the U. S. Public Health Service, will be given at the University of Colorado Medical Center, Denver, October 18-21. The course has been designed to cover in practical fashion the fundamentals of communicable disease control. Although designed primarily for general practitioners in rural areas, the course is open to all physicians. —A short course for physicians on problems of newborn infants will be given October 14-16 by the University of Colorado School of Medicine and the Colorado State Department of Health, Denver. Lectures, panel discussions and demonstrations will be given by members of the faculty on obstetric aspects of prematurity, resuscitation, isoimmunization, psychologic problems developing in prematurely born infants, community planning, interpretation of laboratory findings in the newborn and parenteral fluid therapy. A registration fee of \$10 is required. Inquiries should be directed to Dr. Frode Jensen, Director of Graduate and Postgraduate Education, University of Colorado Medical Center, Denver.

FLORIDA

Typhus Control in Florida.—The state board of health reports that in those Florida counties carrying out organized typhus measures for 1947 a 46 per cent reduction in reported typhus cases was evident over the previous year. In comparison, there was a 64 per cent increase in the combined number of reported cases from those counties where no organized control work was performed. The number of cases of endemic typhus has increased since it first was officially reported in 1918 to a peak of 484 cases in 1944. The state board of health is concentrating its control program in counties where the greatest number of cases have been reported. Rat-proofing of buildings, distribution of poisoned rat bait, rat trapping, promoting better garbage disposal methods and distribution of DDT dust in and around buildings are being used.

GEORGIA

Greensboro Hospital.—Construction of the Minnie G. Boswell Memorial Hospital, the first hospital to be erected in the state under the provisions of the Hill-Burton Act, was recently begun in Greensboro; it is expected to be completed in ten months.

Postgraduate Course in Medicine and Surgery.—Emory University School of Medicine, Atlanta, in cooperation with the Medical Association of Georgia will present a postgraduate course in medicine and surgery October 11-15. The course is designed to present current ideas concerning the diagnostic and therapeutic problems of general practice and may be used in meeting part of the requirements for membership in the American Academy of General Practice. The registration fee is \$10.

ILLINOIS

Incidence of Infectious Diseases.—Venereal diseases are by far the most widely prevalent communicable infections in Illinois. As of August 14, according to the state health department, 10,564 cases of syphilis had been reported. The morbidity report for the first thirty-two weeks of this year shows a 17 per cent reduction in the incidence of tuberculosis. A total of 4,061 cases have been reported so far this year, as against 4,918 in the 1947 period. Marked reductions have also been noted in the acute diseases of the respiratory tract. Only 90 cases of influenza had been reported, as compared with 1,068 in the same period last year. Whooping cough, with 1,517 cases, was a little more than half as prevalent as last year. Diphtheria declined to 74 cases, and typhoid to 59 cases. There were 41,570 cases of measles reported, as compared with 4,018 cases last year. Mumps, with 9,970 cases, is more than twice as prevalent as last year, and poliomyelitis has been responsible for 230 reported cases of illness as against 124 in the 1947 period.

Chicago

Virus and Rickettsial Diagnostic Tests.—The department of bacteriology at Michael Reese Hospital has introduced routine virus and rickettsial diagnostic tests. This hospital is said to be one of the first in this area to offer these tests on a routine basis.

Illinois Faculty Promotions.—Eight members of the faculty of the University of Illinois College of Medicine have recently received professorial promotions. Dr. Cecil A. Krawker has been promoted to the rank of professor of pathology and will also serve as associate pathologist in the university's 428 bed research and educational hospitals. Dr. Fay H. Squire has been made clinical professor of radiology. The rank of associate professor has been given to Dr. Morton I. Grossman, physiology, and Dr. Georgiana D. Theobald, ophthalmology. Assistant professorships have been awarded to the following: Dr. Matthew J. Brunner, dermatology; Hubert R. Catchpole, Ph.D., physiology; Miss Ruth B. Coleman, A.B., medical illustration, and Dr. Joseph S. Haas, ophthalmology.

INDIANA

Dr. Ross to Head Department.—Dr. Alexander T. Ross, assistant professor of neurology and psychiatry in the Indiana University School of Medicine, Bloomington-Indianapolis, has been named to succeed Dr. David A. Boyd Jr., who has resigned as chairman of the department of neurology and psychiatry. Dr. Ross will become a full time member of the staff with the rank of professor of neurology. Appointment of a professor of psychiatry will be made later. Dr. Boyd, professor of psychiatry and chairman of the department for nearly ten years, resigned to become consultant in psychiatry at the Mayo Clinic, Rochester, Minn., in the development of its psychiatric division. Dr. Ross concluded over four years in the Army Medical Corps with an assignment to the Surgeon General's Office and as chief of the neurology branch, Neuropsychiatry Consultants' Division.

KENTUCKY

State Association Meeting.—The Kentucky State Medical Association will meet at the Netherland Plaza Hotel, Cincinnati, September 27-30, under the presidency of Dr. Guy Aud, of Louisville. Guest speakers include:

Waltman Walters, Rochester, Minn., Peptic Ulcer.
Robert A. Lyon, Cincinnati, Prophylaxis of Recurrent Rheumatic Fever.
Philip Thorek, Chicago, Early Surgical Diagnosis.
Lloyd F. Zacharias, Cincinnati, Evaluation of Breech Deliveries.
Virgil D. Hauenstein, Cincinnati, Cardiac Emergencies.
George F. Lull, Secretary and General Manager, American Medical Association, Chicago.

The oration in surgery will be given Tuesday noon by Dr. Thomas H. Milton, Owensboro, on "Surgery and Its Relation to the Public," and the oration in medicine Wednesday noon by Dr. George W. Pedigo Jr., Louisville, on "The Clinical Evaluation of Edema."

MARYLAND

Extension of Medical Care to Low Income Groups.—A program of free doctors' care for the poor, administered by the Baltimore city health department with the state defraying expenses, has been initiated. At first benefits, including surgery, dentistry and medicine, will be made available to those on the Welfare Department's relief rolls, but the services will be extended to persons who earn a living but cannot afford to pay medical expenses. Physicians cooperating in the setup will receive \$7 a year per patient, regardless of the number of visits made. Services will be given in "medical care clinics" at local hospitals, which receive a flat annual \$10 fee per patient cared for. The program is said to have been evolved by the city's medical profession, and, with the exception of the blanket annual fee, is patterned after the medical care system in effect for three years in the twenty-three counties of the state.

Seminars for Health Officers.—A series of seminars in local health administration will be conducted this year to provide regular opportunity for county health officers to discuss their problems. Meetings will be held quarterly in four districts into which the counties have been grouped: north, west, south and east. In each area the quarterly meeting will be conducted by Dr. Ernest L. Stebbins, director of the Johns Hopkins School of Hygiene and Public Health, Baltimore, and Dr. Allen W. Freeman, Baltimore, consultant in public health administration to the state board of health. The program for each session will be formulated by a health officer designated in advance of the meeting, who will prepare and send to the central office an outline of the problems to be discussed. These seminars will not interfere with the annual and quarterly meetings of health officers, bureau chiefs and other personnel that the state department of health has held in Baltimore over a period of years.

MASSACHUSETTS

Board of Registration in Medicine.—At the annual meeting of the Board of Registration in Medicine held July 13, the following officers were elected for the ensuing year: Dr. Gordon M. Morrison, Boston, chairman, and Dr. George L. Schadt, Springfield, secretary. The other members of the board are as follows: Drs. Anthony O. Cardullo, Robert C. Cochrane and Roger T. Doyle, Boston; Charles E. Donovan, D.O., Salem, and Dr. Bancroft C. Wheeler, Worcester.

Research Professor of Medicine.—Dr. Freddy Homburger, associate in the clinical investigation division at the Sloan-Kettering Institute for Cancer Research, New York, has been appointed research professor of medicine at Tufts College Medical School, Boston, to act as head of the cancer research and cancer control units. Dr. Homburger received his medical degree in Switzerland and before joining the Sloan-Kettering staff held fellowships at Harvard Medical School, Boston, and Yale University School of Medicine, New Haven, Conn.

NEBRASKA

Omaha Mid-West Clinical Society.—The Omaha Mid-West Clinical Society's annual assembly will be held at the Hotel Paxton, Omaha, October 25-29. There will be panel discussions on diabetes, gynecology, adolescence, peptic ulcer, antihistaminic drugs, injuries in automobile accidents and the medical expert witness, and a clinicopathologic conference. Among the guest speakers are Morris Fishbein, Richard B. Capps, Oliver E. Van Alyea and Sumner L. Koch, all of Chicago; Benjamin M. Spock and Paul A. O'Leary, Rochester, Minn.; Paul D. White, Boston; James A. Dickson, Cleveland; A. Earl Walker, Baltimore; Charles L. Martin, Dallas, Texas; D. W. Gordon Murray, Toronto, Canada; Robert A. Kimbrough, Philadelphia, and Steven M. Spencer, Swarthmore, Pa.

NEVADA

State Medical Meeting.—The annual meeting of the Nevada State Medical Association will convene at the Hotel Nevada, Ely, September 24-25, under the presidency of Vinton Muller of Reno. Guest speakers include:

- Robert G. Weaver, Salt Lake City, Urinary Calculi.
- Robert C. Martin, San Francisco, Conditions Commonly Missed in the Ears, Nose and Throat.
- Hyrum R. Reichmann, Salt Lake City, Surgical Conditions of the Anorectum.
- O. George Bates, San Francisco, Pediatric Problems in General Practice.
- Floyd F. Hatch, Salt Lake City, Gastric Surgery.
- Frederick C. Cordes, San Francisco, Emergency Treatment of Eye Injuries.
- Fletcher B. Taylor, Oakland, Calif., Medical Follies of 1947.
- LeRoy C. Abbott and Helen Hagey, San Francisco, Prevention of Deformities in Poliomyelitis.

The council meeting Thursday evening will be addressed by Dr. Joseph C. Buntin, Cheyenne, Wyo. The annual banquet will be Friday evening.

NEW YORK

Regional Diabetes Association.—The Rochester Regional Diabetes Association, has been organized to make the best of medical and nursing care available to all persons with diabetes. The group will function in cooperation with the Rochester Regional Hospital Council with headquarters in the Academy of Medicine. Pamphlets will be distributed and physicians experienced in the treatment of diabetes will be available for lectures and other educational services. Dr. Charles B. F. Gibbs and Dr. H. Raymond Drysdale, both of Rochester, are president and secretary-treasurer, respectively. A board of six physicians will serve as directors of the group.

New York City

Brigadier General Walston to Administer Blood Program.—Brig. General Charles M. Walston, U. S. Army, retired, has been named administrator of the American Red Cross Blood Program of the Greater New York Chapters, 4 East Thirty-Seventh Street. He will direct all phases of the program, which seeks through enrolment of volunteer donors to assure a supply of blood for New York's medical needs. General Walston is a graduate of Jefferson Medical College, Philadelphia, and of the Army Medical School, in 1912. He served in both World Wars.

Survey on Lower East Side.—A survey on the Lower East Side, begun in February 1947 and sponsored by the New York University-Bellevue Medical Center, the New York Heart Association, the city department of health, the Board of Education and the U. S. Public Health Service, showed that 754 children have had rheumatic fever, rheumatic heart disease, congenital heart disease or possible heart disease. Dr. Elvira

DeLee-Burke, research associate in the department of preventive medicine at New York University College of Medicine, is directing the work. Directors of the project plan to extend the survey to the entire city.

OKLAHOMA

Fall Meeting of Clinical Society.—The annual meeting of the Oklahoma City Clinical Society will be held October 25-28 at the Biltmore Hotel, Oklahoma City. The program is made up of a clinical pathologic conference, general assemblies, postgraduate courses, round table luncheons, dinner meetings and commercial exhibits. The registration fee is \$15. Guest lecturers will be Drs. Morris Fishbein and John B. Youmans, Chicago; Jerome W. Conn, Ann Arbor, Mich.; Katharine Dodd, Cincinnati; John G. Downing, Boston; Lawrence S. Fallis, Detroit; Arthur B. Hunt and David G. Pugh, Rochester, Minn.; Rudolph H. Kampmeier, Nashville, Tenn.; Frank R. Lock, Winston-Salem, N. C.; William P. Longmire and Allen F. Voshell, Baltimore; Tracy O. Powell, Los Angeles; Harold G. Scheie, Philadelphia; Theodore E. Walsh, St. Louis; Theodore A. Watters, New Orleans, and Owen W. Wangenstein, Minneapolis. Information may be obtained from the Executive Secretary, 512 Medical Arts Building, Oklahoma City.

OREGON

Bone Tumor Registry.—The pathology department at the University of Oregon Medical School, Portland, with the financial assistance of the American Cancer Society, has established a bone tumor registry, to assemble complete case records including the roentgenograms, pathologic material and follow-up data on bone tumor and other bone diseases; to make such material available for study by any qualified doctor of medicine in the state, and to assist physicians in the diagnosis of unusual or obscure bone lesions. Physicians in Oregon are invited to submit completely worked-up cases for the registry. These will be studied by a board of orthopedists, radiologists and pathologists, and reports returned to the submitting physician as early as possible. Cases requiring additional study will be submitted to the Bone Tumor Registry of the Army Institute of Pathology for further opinion. Physicians and surgeons are invited to utilize the study and consultation facilities at any time. The Bone Tumor Registry of the University of Oregon Medical School will supply data to assist the board of health in maintaining statistical records, and it, in turn, will make available to the university and to physicians of the state information gained through maintenance of the registry.

PENNSYLVANIA

Clinical Pathologists Meeting.—The Pennsylvania Association of Clinical Pathologists will hold its fall meeting at the Bellevue-Stratford Hotel, Philadelphia, October 2-3. Papers to be presented will include:

- A. Parker Hitchens, Philadelphia, the Clinical Pathologist and the Public Health.
- George R. Lacy, Pittsburgh, Survey of the Accuracy of Bacteriologic Examinations in Clinical Laboratories.
- Leandro M. Tocantins, Philadelphia, Bone Marrow Biopsy.

There will also be a round table discussion on the training of residents, with Dr. Samuel R. Haythorn, Pittsburgh, as moderator.

Centennial Celebration of State Medical Society.—The Medical Society of the State of Pennsylvania will observe its centennial at the annual meeting at the Bellevue-Stratford Hotel, Philadelphia, October 3-7, under the presidency of Dr. Elmer Hess, Erie. The scientific program will include symposiums on hematology; the thyroid and radioactive isotopes; three "What's New" programs on medicine, surgery and obstetrics and gynecology, and three clinicopathologic conferences. Guest speakers at the general scientific sessions will be:

- Stewart G. Wolf Jr., New York, Physiologic Mechanisms of Psychosomatic Phenomena.
- Elmer C. Bartels, Boston, An Evaluation of Antithyroid Drugs.
- John M. McLean, New York, Corneal Grafting.
- Charles C. Dennie, Kansas City, Mo., Man Defends Himself.
- Bettina M. Carter, M.S., Pittsburgh, Studies on the Rh Hapten in Relation to Rh Sensitization.
- Bradley L. Coley, New York, Early Diagnosis of Tumors of Bone.
- Roscoe P. Kandle, New York, Public Health Activities in Pennsylvania.
- T. Duckett Jones, New York, Rheumatic Fever and Rheumatic Heart Disease Programs of Care.

The state dinner will be held Monday, and the president's reception Wednesday evening. Besides the technical and scientific exhibit, historical exhibits will show the advancement of medicine. The Woman's Auxiliary will hold its annual meeting beginning October 4 at the Bellevue-Stratford.

VERMONT

Cancer Society Formed.—The Vermont Cancer Society, Inc., was organized last spring as a division of the American Cancer Society under the sponsorship of the Vermont State Medical Society. Dr. Benjamin F. Cook, Rutland, was elected president and Mr. John W. Brownlee, Rutland, secretary. The cancer committee of the Vermont State Medical Society, with Dr. Oscar S. Peterson Jr., Burlington, as chairman, was constituted the medical advisory board of the Vermont Cancer Society.

State Medical Society Meeting.—The annual meeting of the Vermont State Medical Society was held September 15-17 at the Hotel Vermont, Burlington, under the presidency of Dr. Benjamin F. Cook, Rutland. Out of state speakers included:

Richard S. Farr, Syracuse, N. Y., Fractures.

C. Stuart Welch, Boston, Trans-Thoracic Approach for Surgery of the Upper Abdomen.

David S. Grice, Boston, Rationale of Treatment of Acute Poliomyelitis.

Harold T. Hyman, New York, Management of Thrombo-Embolic Disease by the General Practitioner.

Elmer L. Sevringhaus, Nutley, N. J., Use of Endocrines in Functional Bleeding.

At the luncheon meeting on Thursday Dr. Alfred Gellhorn, New York, spoke on "The Red Cross Blood Program." Dr. James R. Miller, Hartford, Conn., trustee, American Medical Association, spoke at the annual banquet on "The World Health Organization, Our Concern in the Health of Other Peoples." Two symposiums were on the program, one on fractured pelvis and another on gastroenterology.

VIRGINIA

Establish Department of Legal Medicine.—A department of legal medicine has been added to the Medical College of Virginia curriculum, effective at the beginning of the school term this year. Under the direction of Dr. Herbert S. Breyfogle, Richmond, chief medical examiner of Virginia, the new department will offer courses relating to the collection of scientific evidence for the administration of civil and criminal law and will also engage in research and offer postgraduate work. The first research problem undertaken will be a study of the role of injury in the cause of cancer.

State Medical Meeting.—The Medical Society of Virginia will hold its annual meeting at the John Marshall Hotel, Richmond, October 18-20, under the presidency of Dr. Guy R. Fisher, Staunton. Guest speakers include:

James P. Baker, White Sulphur Springs, W. Va.

Edwin E. Barksdale, Washington, D. C., and George Ellis, Bethesda, Md., Use of the Anti-Histamine Drugs in Dermatology.

Charles S. White, Washington, D. C., Protein Deficiency in Surgical Practice.

Harrison F. Flippin, Philadelphia, Antibiotic and Sulfonamide Therapy.

The banquet will be held Wednesday evening.

GENERAL

Panamerican Convention of Medical Education.—The First Panamerican Convention on Medical Education will be held at the Panamerican Medical Congress in Lima, Peru, December 3-13. The agenda include: (1) report on the status of each respective school of medicine; (2) systems of medical education; (3) the school for postgraduate education; (4) the training and practice of medical specialties, and (5) importance and necessity of research departments.

American Dietetic Association.—The annual meeting of the American Dietetic Association will be held in the Mechanics Building and Hotel Statler, Boston, October 18-22. Sessions will explore results of nutrition research, new methods and technics and progress in community nutrition, diet therapy, food administration and professional education. The program includes a session on new advances in nutrition, another on maternal and child health and two meetings on diet therapy.

Heart Association Employs Fund-Raising Director.—The appointment of Mr. E. J. Ade, technical director for many major war fund drives, as the first fund-raising director of the American Heart Association was announced recently by Dr. Tinsley R. Harrison, president of the association. Mr. Ade will coordinate the activities of national fund-raising committees which are now being established for an expanded 1949 campaign to be climaxed during National Heart Week, beginning next February 14, St. Valentine's Day.

Clinical Congress of Surgeons.—The thirty-fourth Clinical Congress of the American College of Surgeons will be October 18-22, with headquarters at the Biltmore Hotel in Los Angeles. The program of scientific sessions will be supplemented by operative clinics in hospitals, by television and motion pictures, and a four day hospital standardization conference for hospital personnel. Evening symposiums will take up the subjects of cancer, fractures and other traumas, and graduate training in surgery and the surgical specialties. Dr. Clarence M. L.

Crafoord, professor of surgery, Karolinska Mediko-Kirurgiska Institutet, Stockholm, Sweden, will deliver the Third Martin Memorial Lecture Monday evening, on "Some Aspects of the Development of Intrathoracic Surgery." The Annual Fracture Oration will be presented by Dr. Henry C. Marble, Boston, on the following evening.

Grants for Study of Multiple Sclerosis.—The National Multiple Sclerosis Society has made grants totaling \$77,600 to five medical institutions to conduct medical research projects into the causes and control of multiple sclerosis. Included is a fund to establish the second multiple sclerosis research clinic to be financed by the society, opened August 16 at Albany Hospital, Albany, N. Y. The largest grant will go to Tulane University of Louisiana School of Medicine, New Orleans, to finance a three year study of the possible relation between virus infection and the process of demyelination. A grant was voted to the Massachusetts General Hospital, Boston, for a two year project that will be devoted to basic research in myelin degradation and another to Cedars of Lebanon Hospital, Los Angeles, for an investigation into the behavior of the blood-clotting mechanism in multiple sclerosis. The fifth grant was made to the New York University College of Medicine for a study of psychological factors in multiple sclerosis.

Incidence of Poliomyelitis.—According to the U. S. Public Health Service, 1,411 cases of poliomyelitis were reported during the week ending August 28, as compared with 1,312 the previous week. Increases of 10 or more cases in the following named states accounted for an aggregate increase of 110 cases (first figure current week, second figure last week): Minnesota 89, 67; Iowa 57, 37; California 226, 206; Texas 71, 54; Michigan 53, 42; New Jersey 50, 40, and Georgia 18, 8. Decreases of 5 or more cases (an aggregate decrease of 83 cases) were reported in the following states: North Carolina 133, 159; New York 87, 99; Florida 5, 14; Tennessee 18, 28; Kentucky 8, 16; Virginia 31, 38; Ohio 76, 82; Wisconsin 31, 36. The increases listed above and those in a few other states resulted in a net increase of 99 cases over the preceding week. Rhode Island continues to be the only state in which no cases have been reported to date. Cases to date total 11,155, as compared with 10,654 in 1946 and a five year median of 5,239 for the corresponding period.

CORRECTIONS

Treatment of Migraine with Histamine.—In the article by this title in THE JOURNAL, July 24, 1948, the dosage on page 1112, column 1, in the fourteenth line from the bottom, should read 0.7 mg. instead of 0.07 mg.

Address of Dr. R. R. Spencer.—The correct address of the author of the article, "The Meaning of Cancer Research," in THE JOURNAL, Aug. 14, 1948, is Dr. R. R. Spencer, United States Public Health Service, National Institute of Health, Bethesda 14, Md. The address of the author given at the end of this article was that of another physician by the same name residing in Chicago.

Marriages

EDGAR COOPER PERSON JR., New York, to Mrs. Mary Elizabeth Altemus Whitney of Upperville, Va., June 18.

JOSEPH BERNARD SHAPSE, Brooklyn, to Miss Constance Reichert Weiss at West Englewood, N. J., May 30.

THOMAS BENJAMIN JOHNSON, Towanda, Pa., to Miss Ruth Elizabeth Casler of Millbrook, N. Y., June 26.

EDMUND A. STEENBERG, Aurora, Neb., to Miss Patricia MacArthur of Schenectady, N. Y., June 23.

GLENN D. VAN GAASBEEK, Kingston, N. Y., to Miss Evelyn Mae Gerhart at Llanerch, Pa., June 26.

EDWARD FINCH PARSONS, Flushing, N. Y., to Miss Elizabeth Platt Hubbell at Garden City, June 25.

DONALD LLOYD GORDON, New York, to Miss Adlynn McKeel Hartley of Englewood, N. J., May 29.

DONALD WALTER MOLINE, Oakland, Calif., to Miss Jacquelin Lee Sharp of Palo Alto, June 19.

WILLIAM LEWIS HALL to Miss Jo Ann Dillon, both of Columbus, Ohio, May 8.

HARVEY HATCHFIELD, New York, to Miss Judith Lang of Brooklyn, March 20.

BENJAMIN H. OREMLAND to Miss Pauline Turchin, both of Brooklyn, June 27.

Deaths

Guy William Wells * Providence, R. I.; born in Springfield, Pa., July 9, 1891; Cornell University Medical College, New York, 1920; member of the House of Delegates of the American Medical Association from 1934 to 1937, in 1939, 1940, 1946 and 1947; from 1936 to 1941 secretary of the Rhode Island Medical Society and during 1947 president of the Providence Medical Association; served overseas during World War II; specialist certified by the American Board of Internal Medicine; on the courtesy staff of the Roger Williams General Hospital; on the consulting staffs of the Woonsocket (R. I.) Hospital and Miriam Hospital; on the visiting staff of the Pawtucket (R. I.) Memorial Hospital, where he served as chief of the medical staff; on the staffs of the Providence Lying-In Hospital, South County Hospital, Wakefield, Westerly (R. I.) Hospital, the Charles V. Chapin Hospital and the Rhode Island Hospital, where he died June 15, aged 56, of carcinoma of the stomach.

Taliaferro Clark * Medical Director, U. S. Public Health Service, retired, Germantown, Md.; born in The Plains, Fauquier County, Va., May 14, 1867; University of Virginia Department of Medicine, Charlottesville, 1890; entered the U. S. Public Health Service as an assistant surgeon in 1897; at one time supervised immigration, quarantine and related services in the British Isles and continental Europe; appointed medical director, Assistant Surgeon General in 1930 and acted as chief of the venereal disease division until his retirement in 1933; director of the Child Hygiene Investigation in 1915 and the Bureau of Sanitary Service, American Red Cross from 1917 to 1919; member of the International Sanitation Conference in Paris in 1926; delegate to the International Conference on Tropical Medicine at Cairo, Egypt, in 1928; American member of the Office International d'Hygiene Publique; died in the U. S. Marine Hospital, New York, July 3, aged 81.

Edwin Howe Fiske * Brooklyn; born in Baltimore, Jan. 23, 1877; Long Island College Hospital, Brooklyn, 1901; professor of clinical surgery at the Long Island College of Medicine from 1924 to 1935 when he became emeritus professor; formerly clinical professor of surgery at the University and Bellevue Hospital Medical College in New York; served overseas during World War I; a founder and charter member of the American College of Surgeons; consulting surgeon, Bushwick Hospital, Brooklyn, Eastern Long Island Hospital, Greenport, and Mercy Hospital, Hempstead; served as director of surgery and chairman of the medical board at Kings County Hospital, visiting surgeon at the Hospital of the Holy Family, Midwood and Carson C. Peck Memorial Hospital; died June 16, aged 71.

Henry Pelouze de Forest * New York; born in Fulton, N. Y., in 1864; College of Physicians and Surgeons, medical department of Columbia College, New York, 1890; an Affiliate Fellow of the American Medical Association; formerly adjunct professor of obstetrics at the New York Post-Graduate Medical School and Hospital, Columbia University; veteran of the Spanish-American War; served as sanitary inspector for the city health department, police surgeon, chief medical examiner of the Municipal Civil Service Commission and a member of the medical board of the Teachers' Retirement Board; died June 13, aged 83, of carcinoma of the liver.

Henry Andrews Cotton Jr., * Trenton, N. J.; born in Danvers, Mass., Oct. 14, 1907; Johns Hopkins University School of Medicine, Baltimore, 1934; deputy state commissioner of hospitals; interned at the Johns Hopkins Hospital in Baltimore, where he served a residency; formerly resident at Psychopathic Hospital and Jersey City Hospital in Jersey City and the New Jersey State Hospital in Trenton; served overseas during World War II; member of the American Psychiatric Association; died in the Princeton (N. J.) Hospital, June 21, aged 40, of an accidental overdose of sleeping powder.

Owsley Grant * Louisville, Ky.; born in Louisville in 1887; Johns Hopkins University School of Medicine, Baltimore, 1911; clinical professor of urology at the University of Louisville School of Medicine; specialist certified by the American Board of Urology, Inc.; member of the Southern Surgical Association and the American Urological Association; fellow of the American College of Surgeons; affiliated with the Louisville General, Deaconess, Central State, Baptist and Kosair hospitals and the Norton Memorial Infirmary; died July 1, aged 60, of Banti's disease.

John Merlin Alford * Galva, Ill., Hering Medical College, Chicago, 1908; died April 21, aged 61.

Walter Edward Arnold, Tulsa, Okla.; American Medical College, St. Louis, 1909; died May 1, aged 66.

Ulysses S. Bradley, Harris, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1896; died June 21, aged 81, following fracture of the hip.

Charles Brower, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1885; member of the American Medical Association; fellow of the American College of Surgeons; formerly professor of surgery at the University of Nashville Medical Department; served on the staffs of St. Thomas and Nashville General hospitals; died June 24, aged 86, of congestive heart failure.

Robert Ellsworth Brown, Los Angeles; University of Michigan Medical School, Ann Arbor, 1918; served as a medical missionary in China; died May 20, aged 62, of cerebral hemorrhage.

Henry Clay Caldwell, Madison, Wis.; Milwaukee Medical College, 1901; served during World War I; affiliated with the Veteran Administration from 1944 to 1946; died in the Wisconsin General Hospital June 24, aged 73, of cerebrovascular accident and arteriosclerosis.

Richard Henry Carter, Fresno, Calif.; Cooper Medical College, San Francisco, 1895; at one time affiliated with the U. S. Veterans Bureau in San Francisco; served as health officer of Parlier and as assistant county health officer; on the staff of General Hospital of Fresno County; died June 11, aged 77, of heart disease and diabetes mellitus.

John Baptist Casale * Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1913; fellow of the International College of Surgeons; president of the medical board and chief of surgery at St. Michael's Hospital; for a short period medical director of the Columbus Hospital; consulting surgeon at American Legion Hospital; died in the Harkness Pavilion of the Presbyterian Medical Center July 8, aged 57, of cirrhosis of the liver.

Weston Percival Chamberlain * Colonel, U. S. Army, retired, Palo Alto, Calif.; Harvard Medical School, Boston, 1897; fellow of the American College of Surgeons; entered the U. S. Army in July 1898; retired June 30, 1935 for disability in line of duty; formerly chief health officer of the Canal Zone; died in Letterman General Hospital, San Francisco, June 7, aged 76, of arteriosclerosis.

Esmond Austin Childs, Long Beach, Calif.; New York Homeopathic Medical College and Flower Hospital, New York, 1909; died in May, aged 67, of coronary thrombosis.

Charles E. Cole * Jacksonville, Ill.; Northwestern University Medical School, Chicago, 1903; veteran of the Spanish-American War; member of the board of the Morgan County Anti-Tuberculosis League; affiliated with Morgan County Tuberculosis Sanatorium "Oaklawn"; died in the Passavant Memorial Hospital May 17, aged 68, of a hip fracture received in a fall.

Metta Viola Collins, Springfield, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; died June 2, aged 82, of bronchopneumonia and arteriosclerotic heart disease.

William John Crotty * East St. Louis, Ill.; St. Louis University School of Medicine, 1919; past president of St. Clair County Medical Society; on the staffs of St. Mary's and Christian Welfare hospitals; president of the State Savings and Loan Association and director of the Southern Illinois National Bank; died May 22, aged 54, of coronary thrombosis.

Ernest Crutcher, Los Angeles; Vanderbilt University School of Medicine, Nashville, Tenn., 1879; died June 1, aged 90, of carcinoma of the prostate.

Edward Cunat, Chicago; Rush Medical College, Chicago, 1900; fell from the fifth floor window of the Presbyterian Hospital April 21, aged 71.

Michael Henry Dalton, St. Louis; Tufts College Medical School, Boston, 1898; member of the American Medical Association; died May 31, aged 80, of cerebral hemorrhage.

Joseph Paul Davis Jr., Turlock, Calif.; University of Oklahoma School of Medicine, Oklahoma City, 1942; member of the American Medical Association; interned at the General Hospital of Fresno County, Fresno; died May 20, aged 33.

Henry Harrison Deen, Leavenworth, Ind.; Hospital College of Medicine, Louisville, Ky., 1906; member of the American Medical Association; county health officer; served during World War I; major, medical reserve corps, U. S. Army; died May 29, aged 72.

William Charles Ehmke, Willow River, Minn.; Minneapolis College of Physicians and Surgeons, 1906; served as mayor and president of the school board; on the staff of the Moose Lake (Minn.) Community Hospital; died May 9, aged 67, of cerebral hemorrhage.

Bruce Bilo Everall, Monona, Iowa; Drake University Medical Department, Des Moines, 1901; member of the American Medical Association; served during World War I; died May 7, aged 69, of coronary thrombosis.

Charles Flett, Milbank, S. D.; Rush Medical College, Chicago, 1895; member of the American Medical Association; for many years member of the county board of health and school board; on the staff of St. Bernard's Providence Hospital; died May 22, aged 82, of uremia.

Penelope McNaughton Flett, Belmont, Mass.; University of Michigan Medical School, Ann Arbor, 1896; served as school physician; died May 3, aged 85, of arteriosclerotic heart disease.

John Francis Hamilton, Ohio; Miami Medical College, Cincinnati, 1889; died May 25, aged 86.

Francis Augustus Georger, Warrenton, Va.; University of Buffalo School of Medicine, 1913; served during World War I; died May 12, aged 64, of cerebral hemorrhage.

William M. Goodson Panama City, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1916; died May 27, aged 54, of coronary thrombosis.

George Henry Griffin, Greensburg, Pa.; Kentucky School of Medicine, Louisville, 1907; served during the Spanish-American War and World War I; on the staff of Westmoreland Hospital; died May 30, aged 69, of carcinoma of the larynx.

Thomas Edward Graham, Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1907; also a pharmacist; died May 4, aged 65.

E. L. Green, Carpenter, Miss.; Atlanta Medical College, 1895; died in Vicksburg June 25, aged 80.

William David Harvie, Kansas City, Mo.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1889; at one time health officer of Oshkosh, Wis.; served during World War I; died June 1, aged 83, of bronchopneumonia and hematoma of right thigh.

Alfred Hauptmann, Boston; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1905; member of the American Medical Association; specialist certified by the American Board of Psychiatry and Neurology, Inc.; consultant at the Joseph H. Pratt Diagnostic Hospital; died April 5, aged 66, of coronary occlusion.

Maude Ruhl Hill, Cincinnati; Eclectic Medical Institute, Cincinnati, 1894; died in the Holmes Hospital May 18, aged 76.

Samuel Hirsch, Passaic, N. J.; Baltimore University School of Medicine, 1898; member of the American Medical Association; affiliated with Beth Israel Hospital, where he died May 6, aged 71, of coronary sclerosis and diabetes mellitus.

Leon Willet Hyde, Astoria, Ore.; Rush Medical College, Chicago, 1897; veteran of the Spanish-American War; died May 30, aged 74.

J. Sinkler Irvine, Evinston, Va.; University of Louisville (Ky.) Medical Department, 1891; member of the American Medical Association; died May 30, aged 81.

George Summers Johnson, Nashville, Tenn.; Washington University School of Medicine, St. Louis, 1925; associate professor of surgery at the Vanderbilt University School of Medicine; member of the Southern Society of Clinical Surgeons; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; served in the medical corps of the U. S. Naval Reserve during World War II; affiliated with the Vanderbilt and Veterans Administration hospitals; died May 20, aged 49, of extradural hemorrhage due to a fall.

Oren Guy Johnson, Mayville, Mich.; Detroit College of Medicine, 1905; member of the American Medical Association; served overseas during World War I; formerly state senator, and mayor of the town of Mayville; on the staff of St. Luke's Hospital in Saginaw; at one time superintendent of the American Legion Children's Billet; died May 19, aged 75, of gangrene of right leg, arteriosclerosis and hypertension.

Ernest Kinloch Johnstone, San Francisco; University of California Medical School, San Francisco, 1892; formerly served in the regular army; died in the Franklin Hospital May 23, aged 77.

Henry William Kleinschmit Oshkosh, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1914; died May 19, aged 61.

James Archibald Kleinsmid, Phoenix, Ariz.; Rush Medical College, Chicago, 1899; served during World War I; died May 20, aged 71.

Frank Henry Krebs, Philadelphia; Jefferson Medical College of Philadelphia, 1919; died in St. Mary's Hospital May 30, aged 53.

Cary Devall Langhorne, Upperville, Va.; University of Virginia Department of Medicine, Charlottesville, 1897; at one time an officer in the regular navy; veteran of the Spanish-American War; served in the Philippine Insurrection and received a letter of commendation for heroism in action; received the Congressional Medal of Honor for gallantry in action at Vera Cruz during the American Intervention in Mexico; served during World War I; died April 25, aged 74.

Hilliard Lindley, Hollis, Okla.; Southern Medical College, Atlanta, 1891; died April 28, aged 91.

James Thomas Loomis, Long Beach, Calif.; Chicago Physio-Medical College, 1896; at one time practiced in Toledo, Ohio; died May 24, aged 87, of chronic myocarditis.

Herluf Gyde Lund St. Louis; Washington University School of Medicine, St. Louis, 1907; specialist certified by the American Board of Urology; member of the American Urological Association; affiliated with Lutheran Hospital, where he was chairman of the staff for many years and where he died May 26, aged 65, of multiple abscesses of the kidneys and abscess of the prostate.

Robert James McClure Calumet, Mich.; University of Michigan Medical School, Ann Arbor, 1933; served as secretary of the Houghton-Baraga-Keweenaw Counties Medical Society and the Upper Peninsula Medical Society; formerly assistant in otolaryngology at the Yale University School of Medicine in New Haven, Conn., and assistant resident otolaryngologist at the New Haven Hospital and New Haven Dispensary; killed in a private plane crash at Laurium May 4, aged 40.

John O. McFerrin, Jasper, Ark.; University of Arkansas School of Medicine, Little Rock, 1905; died in Little Rock May 25, aged 76.

John V. McKim, Bowen, Ill.; St. Louis College of Physicians and Surgeons, 1895; associate member of the staff of St. Mary's Hospital in Quincy, where he died May 24, aged 75, of carcinoma of the colon.

Wade Calhoon Mitchell, Los Angeles (registered in Oklahoma to practice medicine in 1909 and licensed in Kansas in 1901); died April 7, aged 66, of chronic myocarditis and arteriosclerosis.

Salvatore Moncada, Belleville, N. J.; Regia Università degli Studi di Padova, Facoltà di Medicina e Chirurgia, Italy, 1917; member of the American Medical Association; died May 22, aged 56.

Forney Long Murray, American Falls, Idaho; University of Oklahoma School of Medicine, Oklahoma City, 1937; served as director of the South Central District Health Unit in Twin Falls; died May 26, aged 42, of coronary thrombosis.

Rudolph Victor Naumann, New York; New York University College of Medicine, New York, 1942; interned at the Bellevue Hospital, where he served a residency; served a residency at New York and Presbyterian hospitals; certified by the National Board of Medical Examiners; died April 1, aged 39.

Russell Roy Noice, Miami, Ariz.; University of Minnesota Medical School, Minneapolis, 1915; served during World War I; at one time practiced in Minneapolis, where he was county physician; died April 15, aged 57.

William Bryant Oldham, New Castle, Ky.; Hospital College of Medicine, Louisville, 1905; member of the American Medical Association; county health officer; died April 23, aged 66.

Odd V. Opheim Sioux Falls, S. D.; Rush Medical College, Chicago, 1914; affiliated with the Sioux Valley and McKennan hospitals; died April 29, aged 62, of acute pulmonary edema.

John Green Pittman Jr., Gaffney, S. C.; Medical College of the State of South Carolina, Charleston, 1929; member of the American Medical Association; served during World Wars I and II; died in a hospital at Lancaster May 26, aged 49.

James Norris Plumb, York, Neb.; Rush Medical College, Chicago, 1891; died May 8, aged 80.

Daniel J. Price Columbus, Ohio; Baltimore Medical College, 1902; died May 8, aged 70.

Samuel Puleston, Sanford, Fla.; University of Maryland School of Medicine, Baltimore, 1902; member of the American Medical Association; died in the Riverside Hospital, Jacksonville, May 28, aged 67, of cardiac hypertrophy and arteriosclerosis.

Ermin Levi Ray, Williamsburg, Mass.; University of Louisville School of Medicine, 1914; served during World War I; affiliated with the Veterans Administration Hospital in Northampton; formerly on the staff of the Veterans Administration Hospital in Lyons, N. J.; died May 21, aged 56, in an airplane accident.

Ralph Clifford Reece, Cincinnati; University of Cincinnati College of Medicine, 1946; interned at the Flower and Fifth Avenue Hospitals in New York and the Cincinnati General Hospital, where he died April 7, aged 26.

Thomas Ludford Rennie, Pell City, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1919; member of the American Medical Association; was burned to death May 8, aged 52.

Charles Henderson Rush, Glendale, Calif.; Cotner University Medical Department, Lincoln, Neb., 1894; died April 24, aged 79, of coronary occlusion.

William Schroeder, Thompson, Iowa; Rush Medical College, Chicago, 1901; died May 29, aged 72, of diabetes mellitus.

Mattie Brown Shaw, Ashland, Ore.; Dalhousie University Faculty of Medicine, Halifax, N. S., Canada, 1897; died April 6, aged 74.

Lewis Mayer Shultz, Port Carbon, Pa.; Medico-Chirurgical College of Philadelphia, 1916; served overseas during World War I; died May 30, aged 54, of uremia.

Henry Franklin Smith, Chattanooga, Tenn.; Memphis Hospital Medical College, 1913; died in the Erlanger Hospital May 2, aged 61, of cerebral embolus.

Arthur A. Snyder, McLean, Va.; University of the City of New York Medical Department, New York, 1882; for many years practiced in Washington, D. C., where he was on the staff

of the Garfield Memorial Hospital; veteran of the Spanish-American War; died May 15, aged 88.

Floyd Rodman Stamp, Alliance, Ohio; Tufts College Medical School, Boston, 1912; member of the American Medical Association; served as county health commissioner for many years; died April 27, aged 66.

John Henry Taylor Jr., Trenton, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1927; on the staff of the New Jersey State Hospital, where he died May 2, aged 46, of acute nephritis.

Victor Clifford Tisdal * Elk City, Okla.; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1910; past president of the Oklahoma State Medical Association; veteran of World War I; served as mayor of Elk City and member of the state board of health; formerly owner of the Tisdal Hospital; died in the University Hospital, Oklahoma City, May 18, aged 62, of coronary thrombosis.

Francis Lewis Tribon, Algona, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1893; died May 23, aged 84, of chronic myocarditis.

Luther Brown Turner, Columbus, Ohio; Starling Medical College, Columbus, 1892; on the staff of the Mercy Hospital, where he died April 23, aged 85.

Nellie Smith Vernon, Astoria, Ore.; University of Oregon Medical School, Portland, 1901; served as city and county health officer; died in Portland May 23, aged 80.

KILLED IN ACTION

CAPT. LOUIS COWEN
M. C., A. U. S., 1908-1945

LIEUT. COL. DAN. B. SEARCY
M. C., U. S. Army, 1909-1945

CAPT. ALEXANDER A. ST. CLAIR,
M.C., A.U.S., 1911-1945

Louis Cowen, New York; University of Buffalo School of Medicine, 1935; interned at the Trinity Hospital in Brooklyn; member of the American Medical Association; began active duty as a first lieutenant in the Medical Corps, Army of the United States, in May 1941; promoted to captain; killed in action in Germany March 1, 1945, aged 37.

Dan Beville Searcy * Lieutenant Colonel, M. C., U. S. Army, Lewisville, Ark.; born in Lewisville, Ark., Feb. 12, 1909; Tulane University of Louisiana School of Medicine, New Orleans, 1934; interned at the Shreveport Charity Hospital in Shreveport, La.; commissioned a first lieutenant in the Medical Corps of the U. S. Army on Dec. 1, 1938; transferred to the Air Corps and sent to Carlisle Barracks after graduating from Aviation School of Medicine at Randolph Field, Texas; completed a course for flight surgeons at Walter Reed General Hospital in 1941, was sent to the Philippine area at the fall of Bataan; served in Australia and New Guinea; promoted to lieu-

tenant colonel in December 1942; received the Legion of Merit for services at Del Monte, Mindanao, Philippine Islands, from Dec. 1, 1941 to April 29, 1942; missing in action since Jan. 18, 1943; declared dead as of Dec. 20, 1945, aged 36.

Alexander Armstrong St. Clair, Bluefield, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1936; member of the American Medical Association; interned at the Lankenau Hospital and Children's Hospital of the Mary J. Drexel Home in Philadelphia; later studied surgery in Austria and Hungary; received a certificate from the University of Vienna in the theory and practice of surgery; on the staff of the Bluefield Sanitarium; began active duty as a lieutenant in the medical corps, Army of the United States on Feb. 11, 1941; promoted to captain; reported missing in action since July 13, 1943 on a flight from Mohanbari Air Base, India, to Kunming, China; determined dead Dec. 19, 1945, aged 34.

World Federation for Mental Health

The formation of a World Federation for Mental Health to act in close collaboration with the specialized agencies of the United Nations was announced at a session of the International Congress on Mental Health in London. Membership of the federation is open to organizations whose object is the promotion of mental health and human relations. About one hundred and fifty delegates representing forty-two nations and four colonial territories are responsible for its formation. Dr. J. R. Rees, president of the International Commission for Mental Hygiene, was elected first president of the federation, and Dr. André Repond, of Switzerland, vice president. Dr. Rees was neurologic specialist to the Ministry of Pensions and during the war was consulting psychiatrist to the Army. He is a well known writer on psychiatry.

Physicians Elected Fellows of Royal Society

The highest scientific distinction in this country is the Fellowship of the Royal Society, which is awarded only for original important scientific work. In the case of physicians the recipients are generally workers in experimental subjects, such as physiology and biochemistry, and only very eminent clinicians are so honored. The following members of the medical profession have been elected: Dr. R. A. McCance, professor of experimental medicine in the University of Cambridge, for his contributions to metabolic studies in man; Sir Leonard Parsons, emeritus professor of diseases of children in the University of Birmingham, for his studies in child health and the wasting disorders of children; Dr. W. A. H. Rushton, lecturer in physiology in the University of Cambridge, for his researches on the effects of electrical stimuli on muscles and nerves.

The Prevention of Venereal Disease

The latest report of the Ministry of Health shows an increase during 1945 in the incidence of gonorrhea and syphilis. In a letter to the medical press Lord Horder, president of the National Society for the Prevention of Venereal Disease, points out that this has happened in spite of the expenditure of large sums by the government, through the Central Council for Health Education, in telling the public of the dangers of venereal disease, coupled with treatment after the disease has developed. But the public has not been allowed to learn the important fact that much of the disease is easily prevented. During the great wars the fighting services all over the world, owing mainly to the persistent efforts of the society, were protected (more or less, according to the enthusiasm of the officer in charge) against these diseases by the preventive measures which the society has advocated for thirty years. But all the time the civilian population has been kept in ignorance and hence the increase. The policy of the society is threefold: (1) to educate the public with regard to the fact that disease can be prevented by simple scientific measures; (2) to supply details of such measures, and (3) to secure alteration in the law to enable preventive means to be sold with the necessary instructions.

Lord Horder's letter has provoked dissenting replies in the *British Medical Journal*. It is stated that during the war some medical officers, who pressed prophylactic measures by every means at their disposal, were driven to the conclusion that they had not diminished but increased the rate of infection, because such advocacy increased sexual promiscuity. A venereologist of extensive experience in the Army and Navy, and to a less extent in a large civilian clinic, has found prophylactic mea-

asures futile. The secretary of the Association for Moral and Social Hygiene insists that the only sure preventive is chastity and that any propaganda which obscures this fact is likely to increase promiscuity and hence to increase the dissemination of venereal disease. The armed forces have had for many years easy access to prophylactic packets and are instructed in their use; yet the incidence of venereal disease is always a great worry to the authorities. The troops occupying Germany are instructed in prophylaxis; yet the incidence of venereal disease was 185 per thousand in 1947. It is suggested that these troops are largely responsible for the spread of venereal disease in our civil population.

PARIS

July 30, 1948.

First International B.C.G. Congress

This Congress, which was held at the Paris Pasteur Institute, under the presidency of Dr. G. Guérin, was attended by delegates from almost every nation. More than one hundred communications were read before the four sections.

To the first section was entrusted the experimental study of B.C.G. and of the methods of its administration. Researches on the preparation of B.C.G. in its dry state have been simultaneously undertaken by Ungar and Muggleton (Great Britain), Rosenthal (United States), Kaiser (Austria) and Bretay (France). By his method for desiccating the vaccine at a low temperature, the latter has obtained a powder of B.C.G. keeping for months the vitality of the germs. Among other things, the preventive action of B.C.G. has been demonstrated by the experimental works of E. Bernard and Kreis, who found that guinea pigs previously vaccinated and superinfected with virulent Koch's bacilli respond better to streptomycin than the nonvaccinated ones. In the second section, dealing with the results of the use of B.C.G. in human beings, various methods of vaccination were discussed: Rosenthal's method (United States) of multiple punctures; Negre and Bretay's one of scarifications, especially used in France, and the intradermal route of Wallgren, preferred in Scandinavian countries. Professor Debre reported that in collaboration with the World Health Organisation and the International Fund for the Relief of Infancy a "pilot station" is being created in Paris for the systematic study of the differences between the various technics of vaccination. This station will also be of use for the instruction of doctors and nurses. The work of the third section concerned the results obtained with B.C.G. in veterinary practice. It has been proved that B.C.G. vaccination on a large scale could largely diminish the extension of tuberculosis in cattle; for instance, in France, where 40 per cent of the cattle are tuberculin positive. The fourth section dealt with the conditions of application of B.C.G. in the field of preventive hygiene. Tonell reported the results of vaccination in a Swedish district of 100,000 inhabitants. Thanks to systematic vaccination in primary and secondary schools (18,000 vaccinations) from 1935 to 1946, no tuberculous meningitis has been observed in this district, and the mortality rate, which was 6 per 10,000 up to 1939, decreased to 2.6 per 10,000 in 1946. As emphasized by Wallgren and Guilbaux, the vaccinated patient must be kept free from contagious contacts for several months in order to realize immunization.

The congress then passed unanimously, among others, the following resolutions: that over ten million vaccinations practiced in the whole world for twenty-five years confirm the absolute innocuity of B.C.G. vaccination in human beings; that B.C.G. vaccination constitutes the most effective means of preventing tuberculosis; that the vaccine B.C.G. strain used in all countries originates from the Paris Pasteur Institute; that the technic confirmed by tests in Paris at the Pasteur Institute insures its vitality; that the congress recommends the introduction of the vaccine through the skin, the modes of applica-

tion of which are varied; that the congress does not exclude the oral administration for practical reasons; that the congress recommends the revaccination of subjects whose cutaneous sensitivity to tuberculin has disappeared; that the congress considers urgent as widespread a diffusion as possible of the B.C.G. vaccination; that the congress recommends the development of all other prophylactic measures employed in the fight against tuberculosis.

TURKEY

(From Our Regular Correspondent)

ANKARA, Aug. 16, 1948.

Streptomycin in Tuberculous Meningitis

Not until the middle of 1947 was it possible to obtain streptomycin for the treatment of tuberculous meningitis. The price was 15 Turkish pounds or \$4.80 for 1 Gm., but within a few months the black market was selling it for \$9.00, and as a result during June and July 1948 no streptomycin was available at the Istanbul, the Izmir or the Ankara pharmacy. During the war years tuberculosis greatly increased; hence the government recently granted \$250,000 for the purchase of American streptomycin. In view of the scarcity of the drug, its distribution is at present under the supervision of the Ministry of Health. Health officers are responsible for its distribution in the provinces.

Prof. Dr. Ihsan Hilmi Alantar of the Istanbul Children's Hospital reports on the use of streptomycin in 19 cases of tuberculous meningitis. All 19 children belonged to well to do parents who had been able to procure the new drug. Eight of the 19 patients were girls and 11 were boys; their ages ranged from 2 to 12 years. In 18 of the patients another form of tuberculosis was concomitant with meningitis. The clinical diagnosis in all 19 patients was verified by the tuberculin test, test of the cerebrospinal fluid, or the inoculation of animals. In all 19 patients the albumin content of the cerebrospinal fluid had risen. The Pandy test elicited a clearly positive reaction, and the lymphocytes ranged from 12 to 640 per cubic millimeter. Löwenstein cultures were positive in 3 cases. Of the 11 animals inoculated 3 contracted tuberculosis. Of the 19 patients some received a total of 15 to 20 and others from 50 to 120 Gm. of streptomycin; several of the latter are still under treatment. The patients received an average daily dosage of 1 Gm. of streptomycin; older children and those with the most serious cases 2 Gm. of streptomycin, this dosage being continued as long as possible. Intramuscularly and intrathecal routes were used; the daily dosage given by the intrathecal route was 0.1 to 1.5 Gm. In several cases the therapy had to be abandoned temporarily because the children could no longer bear the repeated injections, or when complications like severe headaches, vomiting, excitement or insomnia arose. There were intervals of two weeks to more than two months. Edema, redness and swelling at the point of injection appeared in almost all 19 patients, especially in extremely small children, requiring a change of injection point. There were several infiltrations and one sterile abscess; in 3 patients urticaria appeared; no true nephritis was observed, but in 3 cases albuminuria. The streptomycin affected the vision of 11 patients. In many papillary stasis occurred; in 5 of the latter greatly weakened visual perception replaced the papillary stasis, so that in one 18 month old child complete atrophy of the visual nerve occurred. The streptomycin therapy was discontinued and the patient was given a large dosage (3.025 Gm.) of vitamin B₁ injection, and the vision returned. In 1 patient symptoms of mastoiditis developed toward the end of the therapy. In several patients whose condition on admission was grave cerebral paralysis soon developed, and in several others it developed later. Of the 19 patients 5 fully recovered; 2 patients are still under treatment with hope of full recovery, and 12 patients whose condition on admission was very serious did not recover.

BELGIUM

(From Our Regular Correspondent)

Aug. 7, 1948.

Medical Meetings at Brussels

More than five hundred physicians and surgeons of Belgium, France, Great Britain, United States, Switzerland, Holland, Luxemburg, Portugal, Greece, Italy, Czechoslovakia, Iran, Canada and the Dominican Republic convened in Brussels for the twenty-second session.

The success was due to the cooperation of the scientific societies in arranging their meetings to coincide with the medical meetings. There are to be mentioned the International Association of Medical Electronics, the Meetings on Dentistry, the extraordinary session of the Belgian Medical Society on Physical Education and Sports, the extraordinary session of the Belgian Society of Scientific Studies on Tuberculosis and Pneumology, of the Belgium Society Against Rheumatism and the extraordinary session of the Medico-surgical Section of the National Society of the Belgian Railroads.

Among numerous scientific reports presented were the following: Is Intelligence Electronic? by Professor Dacos; Ideas Relating to Physical and Biologic Electronics, by Professor Rylandt, who was inclined to connect his data to chronaxia; Biology of Physical Training, by Professor Pierre Combemale; Special Indications for Streptomycin in the Course of the Treatment of the Tertiary Forms of Pulmonary Tuberculosis in the Adult, by Dr. Jeanneret; The Resuscitation of the Heart, by Professor Mercier Fautoux; Observations on Carcinoma of the Lung, by Dr. C. Price Thomas; The Destructive Effect of Microwaves in Biology: Can They be Employed as War Weapons? by Dr. Victor Tomberg; Recent Progress in Chemotherapy of Cancer, by Dr. Alexander Haddow.

Finally, a conference was held by General Sicé, professor of tropical pathology at the University of Basel. It is said that General Sicé plays an important role in the approach of the Tchad (French colony in the African Sudan) and Equatorial Africa to the Free French Forces. He also assumed the difficult task of sanitary organization of the African campaign for these forces. He spoke on the combat of dehydration and dechloridation as the result of extreme heat.

International Union of Railroad Physicians

The National Society of Belgian Railroads has organized under the auspices of Dr. Huybrechts at a scientific session, during which the medical chiefs of the great networks of France, Holland, Switzerland and England with the Council of Administration prepared the way for an international union of railroad physicians. The following passages are from the paper presented by M. Verbist, Minister of Public Health, who epitomized the tendencies with regard to the organization of medicine in Belgium:

It is with good reason that physicians defend, under all circumstances, liberty of choice and professional secrecy as the essential conditions of the practice of their art. Without liberty of choosing the physician, the nurse and the institution of medico-social care or assistance, there is no longer any truly humane medicine. Our constant care in all regulations which we take is to reconcile the requirements of technique and those of liberty. We are convinced that to ameliorate everywhere the health and well-being is the first and the most important contribution which one can make today to social peace. As long as men and women and children die of hunger in the world or are struck down by disease and destitution all desperation and all catastrophes are possible and civilization is menaced. It is generosity and fraternity between peoples which can save a dangerously troubled world. Efficiently to preserve the health and well-being of human beings is to safeguard peace.

National Exhibit of Physician Artists

The third National Exhibit of physician painters organized by the Circle of Art and Medicine with the collaboration of the Belgian Chemical Society was opened at Brussels. It has been said that this is a curious exhibit of distinguished amateurs. More than twenty painters and sculptors have combined their works in the beautiful rooms of the Artists' Circle of Brussels. Many of these amateurs have shown serious qualities, and it is interesting to see this movement develop year after year.

Council on Medical Service

RÉSUMÉ OF ACTIVITIES OF CONSTITUENT ASSOCIATIONS AND COMPONENT SOCIETIES

A preliminary survey has been made of state association and county society activities which may serve as a basis for compiling more detailed information in the future, particularly on organization activities as they refer to the National Health Program of the American Medical Association.

Constituent Associations

Following is a brief résumé of replies received from 45 of the 53 constituent medical associations, which consist of 48 state medical associations, the District of Columbia and the four territorial medical associations. For the purpose of simplicity, the terms constituent and state are used interchangeably in this résumé.

Committees To Work With Council On Medical Service.—Direct contact with the state medical associations is recognized as a necessity by the Council. In fact, soon after completing its organization, the Council requested each state association to appoint a committee, either new or existing, to work with the Council. These committees were then invited to meet with the Council—usually five or six states meeting together in some central place. In this manner the regional conferences of the Council on Medical Service were started. Their purpose is to learn of the views and problems of the state medical associations and present to them the views and problems of the American Medical Association. Of the 45 state associations answering the questionnaire 31 have committees to work with the Council on Medical Service.

Organization.—The first state medical association to organize formally was the Medical Society of New Jersey (1766); the most recent was the Alaska Territorial Medical Association (1925). Fourteen were organized prior to the formation of the American Medical Association. The number of associations organized during the Civil War period (1851-1875) is greater than during any other twenty-five year period.

A majority (39) of the associations are corporations, incorporated under state or territorial laws. Incorporation has definite advantages for a medical organization, particularly when its activities extend beyond the purely academic field, when it holds or owns property and when it has a sizeable budget and operating personnel.

While almost every state medical association has a house of delegates composed of physicians selected by the component medical societies, to carry out the legislative decisions most associations have a smaller group elected by the house of delegates. The range in the number of members on these governing boards is from 5 to 21, with about one half of the associations (26) having boards of less than 15 members.

All of the 45 associations, excepting Alaska, reported having at least one part time employee; all but 7 have full time employees. A total of 333 persons are on association payrolls, of whom 270 are full time and 63 are part time.

Membership.—Membership in constituent medical associations, except for the territories and the District of Columbia, is dependent on membership in the component county or district medical societies. Physicians do not join either the constituent medical associations or the American Medical Association; they join the county medical society and are "certified" to the state, which, in turn, reports them to the American Medical Association. The 45 state associations answering the questionnaire reported memberships ranging from 43 (Alaska) to 21,786 (New York). Only 13 have less than 1,000 members, while 7 have a membership of more than 5,000.

Annual dues paid by state association members range from \$5 in Mississippi to \$60 in California. In general, however, the dues are rather low compared to other organizations to which physicians belong, a majority being less than \$25 a year. Each state association seems to set its dues to provide sufficient income to meet its own idea of necessary activity. With one exception, the 7 associations with over 5,000 members have

annual budgets of over \$100,000. Those in the 2,500 to 5,000 membership group seem to require a minimum budget of \$50,000 annually. In associations of less than 2,500 members, no general requirement is evident.

Scientific Activities.—In promoting scientific education in the field of medicine, the state associations continue to fulfil their proper function.

As one activity in this field, 36 state medical associations publish scientific journals. In addition, 11 others participate with one or more associations in publishing a journal. In every instance these journals are devoted primarily to scientific medicine, although most of them publish official actions of the association, news notes from the component county societies and papers or items on social medicine.

Of the 45 associations reporting, 34 provide or make postgraduate programs available for their members. Three are organizing or are in the process of organizing postgraduate programs.

Professional and Public Relations.—The state medical associations are recognizing more and more the need for a planned public relations program to explain the achievements of medicine to the public. Twenty-nine associations reported a public relations program in operation, and 3 are in the process of organizing one. Although these are public relations programs, much of the activity is directed toward physicians; to a considerable extent, then, they are also professional relations programs. In fact, several associations are concentrating on contacts with the profession in order to lay the groundwork for future activity in the field of public relations.

The secretaries' conference has been a regular activity of several state associations for many years. More recently, however, the National Conference of County Medical Society Officers has directed an increased attention toward this particular activity. At present 18 state associations sponsor a secretaries' conference, thus indicating a growing awareness of the need for indoctrinating the officers of the component county medical societies.

News letters are becoming popular among the state medical associations. When the Council on Medical Service began publishing its *News Letter* five years ago, only a few state associations were using this medium to keep in touch with their members. Fourteen now publish regular news letters.

A speakers' bureau can be an important activity, bolstering the scientific programs of the county societies as well as serving the public. That this activity has not been explored to its limit is shown by the fact that only 16 associations reported such a bureau in operation, while 3 reported one in process.

The widespread interest in health councils has not had any particular effect on the formation of state health councils. Twenty state associations report participation in health councils, most of which have been in operation for several years. An additional 4 associations reported health councils in process.

Over one half of the state health councils are limited to representatives of the various professions: medicine, dentistry, pharmacy, etc. In this they differ from the popular conception of a health council, which is composed of representatives of all groups, professional and lay.

Component Societies

For the purpose of tabulation the replies from the county societies have been divided into two groups. Group I refers to replies received from county medical societies having a regular headquarters office and employing lay personnel. Group II refers to replies received from societies which do not employ lay personnel. Tabulation of the information received has been made as brief as possible. The names of specific county societies have been omitted in the tabulation of various activities, but will be made available to physicians or society executives on request.

Organization.—Eleven societies reported owning their own building; in addition, one society is raising funds for a building, and another is considering a building program. Other societies in group I are housed as follows: 36 rent offices and 18 use other facilities, such as hospitals and medical libraries.

Sixty-seven of the 159 societies replying employ lay personnel, and they are in 29 of the 48 states. In 52 of these societies the

lay personnel is listed as full time and in 15 as part time. Some are full time executive secretaries; others are librarians, and a few are listed as part time secretaries. Thirty-six employees listed as executive secretaries are men, and approximately 20 are women.

A few counties in group II have offices, most of them requiring space only for their scientific meetings. However, 6 state that they rent offices; one owns its own building; one has plans under way for building its own headquarters, and another indicated that funds were being accumulated for a building program.

Considering the functions and responsibilities of the county societies, it is surprising how much is accomplished with so little in funds. While the annual dues range from nothing to \$50, almost 60 per cent of the 159 societies reporting collect \$15 a year or less per member. The average physician pays more than this for a day of recreation.

Scientific Activities.—The scientific meeting is one of the county medical society's important functions. Most county medical societies were organized for the purpose of providing their members with an opportunity to keep pace with the scientific medical advancements, and 115 of the 159 societies reporting have a monthly meeting schedule.

While county medical societies continue to sponsor regular scientific meetings, the declining attendance at such meetings is an unsolved problem. The increasing number of hospital meetings, easy transportation to medical centers and the pressure on the physicians by outside sources all contributed to the reduction of attendance at the county society programs. The Council asked the questions "What topics draw best" and "What topics draw least." In answer to the first question a majority of the societies in both groups I and II stated that "general medical programs of interest to general practitioners" draw the best attendance. In answer to the second question, an equally large majority in both groups answered that papers on "specialty subjects" or "nonmedical subjects" draw the least. Other programs listed as well attended are those presenting "recent advances in medicine" and conducted by "well known guest speakers." "Research papers" and "local speakers" were not popular to the general membership.

In addition to the regular scientific meetings, many county societies have organized or make available special postgraduate programs for their members. In group I, 36 societies reported that postgraduate programs were available to the members. In group II, 38 societies reported that postgraduate programs were available to the membership.

The availability of medical library facilities is most important to the present day physician. As a result, most of the medical societies serving the larger cities have either developed their own medical libraries or have made provision for the use of medical library facilities on the part of their membership. Of the 67 county societies reporting in group I, 24 have their own libraries and 32 state that facilities are available to their members. The replies show that physicians in the smaller communities also have library facilities available to them. Of the 92 societies in group II reporting, 15 have their own libraries and 42 have other medical library facilities available to their members.

Other Activities.—Following is a tabulation of other activities carried on by the medical societies in both group I and group II.

Activity	Number of Societies Group I	Group II

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Ruptured Blood Vessel in Eye Due to Strain.—This was an action for the recovery of a workmen's compensation award for an eye injury which occurred during the course of the petitioner's employment. From the granting of an award, the employer appealed to the Supreme Court of Oklahoma.

The petitioner was employed as a tool dresser in a well-drilling operation. While lifting a heavy beam of about 100 pounds a dark spot suddenly developed in his left eye, which nearly blinded him. It subsequently developed that the strain of lifting had so increased his blood pressure as to cause the rupture of a blood vessel in his eye, with the result that he became industrially blind. The petitioner's eye specialist admitted that an existing tubercular condition had weakened the walls of the blood vessels in the eye, but he stated definitely that the injury was due to the lifting of the beam.

The employer contended that the strain of lifting the beam was not an unusual or extraordinary strain, but was an ordinary occurrence in connection with the petitioner's work and that therefore the petitioner did not sustain an accidental injury as that term has been defined by other decisions of the Supreme Court of Oklahoma. The court, however, pointed out that the term "accident" as employed in the compensation acts is broad enough to include an injury from muscular strain or physical overexertion, such as hernia, or rupture, or bursting blood vessels, even though the physical condition of the employee is such as to predispose him to the injury. In the instant case, the Supreme Court continued, the evidence sufficiently showed a strain which, according to the testimony of the petitioner's physician, led directly to the hemorrhage in his eye. The strain of lifting the beam, while lifting was frequently undertaken by the petitioner, was not what could be termed an ordinary occurrence. We have frequently held, the Supreme Court concluded, that an injury occasioned by a strain which causes a dormant or latent condition to light up is an accidental injury within the workmen's compensation act. Accordingly the award in favor of the petitioner was sustained.—*Special Indemnity Fund v. McFee*, 193 P. (2d) 301 (Okla., 1948).

Medical Motion Pictures

FILM REVIEW

Trichomonal and Monilial Vaginitis. Pathology—Diagnosis—Treatment. 16 mm., color, sound, 1,500 feet, (1 reel), showing time forty-one minutes. Prepared in 1947 by J. P. Greenhill, M.D., Cook County Hospital, Chicago. Produced by the Medical Film Guild, New York through a grant from the G. D. Searle & Co., Chicago. Procurable on loan from The Medical Film Guild, 167 West Fifty-Seventh Street, New York 19.

The film presents with considerable detail an outline of the diagnosis and treatment of trichomonal vaginitis. Included are a discussion of laboratory diagnostic procedures and several scenes depicting an ancient aspect of part of the history of vaginal infection. The latter could be omitted, as the scenes tend to detract from the main subject of the film.

The photography is good except for the photomicrographs. The narration is not undertaken by a professional. Some criticism can be directed at the length of the film, as lengthiness encourages unnecessary details. The diagnosis and treatment of trichomonal vaginitis may not always be as simple as depicted in the film, nor is the percentage of cases probably as high as indicated. Furthermore, the danger of contamination from the rectum by the method of wiping the anus, as well as the comparatively uncommon symptoms, general weakness and malaise, has been overemphasized. Air embolism might occur after the use of the demonstrated squirting device. While other criticisms are indicated the film does offer information that the general practitioner may welcome. It will not be especially suitable for the classroom in medical schools because of its length and limited discussion.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I & II.* Various Centers, Feb., June, and Sept., 1949. *Part II.* April, 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa. *Part III.* Boston & New York, Autumn. Sec., Dr. J. S. Rodman, 25 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written.* Various Centers, Jan. 21, 1949. Final date for filing application is Oct. 1. Oral, Philadelphia, Oct. 10. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Oct. 18. Oral, Chicago, Oct. 13-15; Philadelphia, Nov. 3-5; San Francisco, date not set. Candidates not taking these special oral examinations will have no opportunity for admission next year. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part I.* Various Centers, Feb. 4, 1949. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 1.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral.* Chicago, Oct. 6. *Written.* St. Louis, Oct. 15-19. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPEDIC SURGERY: *Part I.* Various Centers, April & May. Final date for filing application is Dec. 31. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral.* Chicago, Oct. 5-8. New York City, Spring, 1949. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PATHOLOGY: Chicago, Oct. 8-9. Final date for filing application is Oct. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

AMERICAN BOARD OF PEDIATRICS: *Oral.* Atlantic City, Nov. 17-19. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines, Iowa.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York City, Dec. 13-15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written.* Various Centers, March 1949. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 28-30, 1949. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

ARKANSAS: * *Little Rock.* Nov. 4-5. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic Examination.* Little Rock, Nov. 4. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral.* Los Angeles, Nov. 20-21. *Written.* Sacramento, Oct. 18-21. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

COLORADO: * *Endorsement.* Denver, Oct. 5. Final date for filing application is Sept. 18. Sec.-Treas., Dr. Walter W. King, 831 Republic Bldg., Denver 2.

CONNECTICUT: * *Examination.* Hartford, Nov. 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic Examination.* Derby, Nov. 9-10. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

FLORIDA: * *Examination.* Jacksonville, Nov. 28-30. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

GEORGIA: *Examination.* Atlanta, Oct. 12-13. *Endorsement.* Atlanta, Oct. 14. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

GUAM: *Endorsement.* Agaña, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

IDAHO: Boise, Jan. 19-12. Dir., Bureau of Occupational Licenses, Miss Estella S. Mulliner, State House, Boise.

ILLINOIS: Chicago, Oct. 5-7. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

INDIANA: *Examination.* Indianapolis, June 1949. Sec., Board of Medical Registration & Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

IOWA: * *Examination.* Des Moines, Dec. 6-8. *Endorsement.* Des Moines, Oct. 4. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

KANSAS: Topeka, Dec. 15-16. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: *Examination.* Louisville, Dec. 13-15. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

LOUISIANA: *Examination.* New Orleans, Dec. Sec.-Treas., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans 12. *Homeopathic Examination.* Baton Rouge, subject to call. Sec., Dr. F. H. Hardenstein, 715 Pere Marquette Bldg., New Orleans.

MAINE: Portland, Nov. 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Examination.* Baltimore, Dec. 14-17. *Endorsement.* At the discretion of the Board. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, Dec. 7-8. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: *Examination.* Boston, Nov. 16-19. Sec., Board of Registration in Medicine, Dr. G. L. Schadt, 413 E. State House, Boston.

MICHIGAN: * *Examination.* Lansing, Oct. 13-15. *Endorsement.* Oct. 12. Sec., Dr. J. E. McIntyre, 203 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, Oct. 19-21. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSISSIPPI: *Reciprocity.* Jackson, Dec. 6. Exec. Officer, State Board of Health, Dr. Felix J. Underwood, Jackson.

MISSOURI: St. Louis, Oct. 25-27. Exec. Sec., Mr. John A. Hailey, P.O. Box 4, Jefferson City, Mo.

MONTANA: Helena, Oct. 4-6. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEVADA: Carson City, Nov. 1. Sec., Dr. G. H. Ross, Industrial Bldg., Carson City.

NEW JERSEY: *Examination.* Trenton, Oct. 19-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Santa Fe, Oct. 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

NEW YORK: *Examination.* Various Centers, Sept. 27-30. Sec., Dr. J. L. Lochner, Jr., 23 South Pearl St., Albany 7.

OHIO: *Examination.* Columbus, Dec. *Endorsement.* Columbus, Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * *Reciprocity.* Oklahoma City, Oct. 24-25. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: * *Examination.* Portland, Jan. 1949. *Endorsement.* Oct. 15-16. Final date for filing application is Oct. 1. Exec. Sec., Mr. Howard I. Bobbitt, 608 Failing Bldg., Portland.

PENNSYLVANIA: *Examination.* Philadelphia, Jan., 1949. Act. Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

RHODE ISLAND: * *Examination.* Providence, Oct. 7-8. Chief, Div. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: *Endorsement.* Oct. 4. Sec., Dr. N. B. Heyward, 1329 Blandford St., Columbia.

SOUTH DAKOTA: * Pierre, Jan. 18-19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

TENNESSEE: * Memphis, Sept. 29-30. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

TEXAS: Fort Worth, Nov. 4-6. Sec.-Treas., Dr. M. H. Crabbs, Medical Arts Bldg., Fort Worth.

UTAH: *Examination.* Salt Lake City, July. *Endorsement.* Oct. 4. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VERMONT: *Examination.* Burlington, Feb. Sec., Dr. F. J. Lawlis, Richford.

VIRGIN ISLANDS: *Examination.* Charlotte Amalie, Dec. 8-9. Comm., Dr. Christian R. Moorhead, Charlotte Amalie.

VIRGINIA: *Examination.* Richmond, Dec. 3-4. *Endorsement.* Dec. 2. Sec., Dr. K. D. Graves, 30½ Franklin Road, Roanoke.

WASHINGTON: * Seattle, Jan. Sec., Dept. of Licenses, Miss Virginia Witherspoon, Olympia.

WEST VIRGINIA: Charleston, Oct. 4-6. Comm., Public Health Council, Dr. N. H. Dyer, State Dept. of Health, Charleston.

WISCONSIN: * Madison, Jan. 11-13, 1949. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls, Wis.

WYOMING: *Examination.* Cheyenne, Oct. 4. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: *Examination.* Tucson, Sept. 21. Sec., Mr. Francis A. Roy, Univ. of Arizona, Tucson.

ARKANSAS: *Examination.* Little Rock, Oct. 5. Sec., Mr. L. E. Gebauer, 1002 Donaghy Bldg., Little Rock.

CONNECTICUT: *Examination.* Oct. 9. Exec. Asst., Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

DISTRICT OF COLUMBIA: *Examination.* Washington, Oct. 18-19. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington, D. C.

FLORIDA: *Examination.* Gainesville, Nov. 6. Final date for filing application is Oct. 25. Mr. M. W. Emmel, University of Florida, Gainesville.

IOWA: Des Moines, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

MICHIGAN: *Examination.* Ann Arbor and Detroit, Oct. 8-9. Sec., Miss Eloise LeBeau, 1510 West Allegan St., Lansing.

MINNESOTA: *Examination.* Oct. 5-6. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

NEBRASKA: *Examination.* Omaha, Oct. 5-6. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln.

NEW MEXICO: *Examination.* Santa Fe, Sept. 19. Sec., Miss Margaret Kilkenny, 110 W. Houghton St., Santa Fe.

OKLAHOMA: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination.* Portland, Dec. Sec., Basic Science Examining Committee, Dr. C. D. Byrne, Univ. of Oregon, Eugene.

SOUTH DAKOTA: *Examination.* Vermillion, Dec. 3-4. Sec., Dr. G. M. Evans, Yankton.

TENNESSEE: *Examination.* Memphis & Nashville, Sept. 20-21. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

WASHINGTON: Seattle, Jan. Sec., Dept. of Licenses, Miss Virginia Witherspoon, Olympia.

WISCONSIN: *Examination.* Madison, Sept. 25. Final date for filing application is Sept. 18. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Treatment of Hypertensive Vascular Disease with Rice Diet. W. Kemp-
ner.—p. 545.
*Low Salt Diets and Arterial Hypertension. H. A. Schroeder.—p. 578.

Thirst in Diabetes Insipidus.—Holmes and Gregersen studied 5 cases of diabetes insipidus in order to evaluate the mechanism of polydipsia under the following conditions: (1) water ad libitum, (2) pitressin therapy, (3) the forcing of fluids and (4) ingestion of salt. During intense thirst there was a reduction of salivary flow. When thirst was abolished by pitressin therapy or by the forcing of fluids, the salivary flow increased to normal values. These observations are consistent with the "dry mouth" theory of thirst. Pitressin therapy or the forcing of fluids resulted in an increase in plasma volume and extracellular volume over the values observed for untreated diabetes insipidus. The thirst mechanism in diabetes insipidus is similar to that observed in simple dehydration and is caused in this instance by the severe polyuria. This is confirmed by the observations that pitressin therapy or the forcing of fluids alleviates thirst and produces increases in plasma and extracellular volume and in salivary flow similar to that observed after ingestion of water in dehydration. Salt, while it may be effective in maintaining plasma volume and available fluid at the same levels as observed under pitressin therapy and when fluids are forced, does not abolish the thirst of diabetes insipidus; on the contrary, it increases the polydipsia. The reaction to salt is the same as that seen in the normal person.

Low Salt Diets in Hypertension.—Schroeder discusses some of the difficulties in the use of low salt diets in the management of hypertension. The possible role of the adrenal cortex in arterial hypertension and its relation to disturbances in tension and its relation to disturbances in salt balance are considered in the light of experimental and clinical evidence. While many subjects respond favorably to rigid restriction of salt by

lowering of blood pressure, psychotherapeutic influences may play a large part in this change in some. If subjects are adequately controlled, the change to be expected is not great and may be absent in patients with severe hypertension in whom therapy is most needed. It is possible that patients who do respond favorably to this diet exhibit a different type of hypertension in which the adrenal cortex is overactive. The mechanism of the response is not understood. No special advantage has been demonstrated in the use of a diet exclusively composed of rice, fruit juices and vitamins, as compared with a normal diet with a similar content of salt, and this diet has several disadvantages.

In Vitro Fertilization of Human Eggs.—Menkin and Rock performed in vitro insemination experiments with human eggs. Fertilization was obtained and cleavage induced in three experiments. The eggs were recovered from ovarian tissue removed from 3 women between the ages of 31 and 38 years on whom complete hysterectomy and right salpingo-oophorectomy were performed on the tenth, the eleventh and the twelfth day of the cycle. The eggs were obtained from follicles of the extirpated ovary, one to four and one-half hours following oophorectomy. After rapid transfer through three portions of sterile Locke's solution, the eggs were pipetted into a Carrel flask containing 3 cc. of serum prepared from the blood of the egg donor. The eggs were then placed in the incubator at 37.5 C. After an incubation period of twenty-two and one-half to twenty-seven hours the eggs were rapidly transferred through small amounts of Locke's solution in three watch glasses. In the third watch glass were then pipetted a few drops of a suspension of spermatozoa which had been at room temperature for two hours and forty-five minutes to four and one-half hours after ejaculation. The watch glass containing the ovum and spermatozoa was observed for one hour under the microscope. The spermatozoa were clearly seen to travel through the interstices of the loose cellular formation surrounding the egg, and many were noted in active motion around the pellucid zone. That was followed by culture of the preparation in human blood serum for forty and one-half hours to forty-six hours. When examined at the end of the incubation period two of the eggs were found to be in the two-cell stage, and two in the three-cell stage. The time relations in these experiments are in general accord with those reported previously for the in vivo fertilized tubal monkey egg cultured in vitro, as well as for in vivo fertilized mouse eggs studied at different intervals after copulation.

Vaginal Absorption of Penicillin.—Abel and his co-workers studied the absorption of penicillin calcium from the vagina in 39 women who were divided in four groups in whom blood level studies were conducted. In 10 patients between the ages of 23 and 59 years, who had vaginitis, 100,000 units of penicillin

General Hospital during the war, *Actinomyces* organisms were isolated from the sputum in 109 of 240 patients. They were also isolated from exudate obtained bronchoscopically in 65 of these 109 patients. The exudate aspirated from pulmonary abscesses in 6 patients, and from the sinus tracts of 2 patients, also contained *Actinomyces* in combination with other organisms. Thirty-seven of the 65 patients with *Actinomyces* organisms in bronchial exudate had bronchiectasis with varying degrees of pneumonitis. The *Actinomyces* organisms in patients with bronchiectasis were felt to be saprophytic and not clinically important under aerobic conditions. In another 8 patients the only apparent disease was a moderately severe chronic bronchitis. There was roentgen and clinical evidence of either aspiration pneumonia, pulmonary abscess or extensive pulmonary suppuration in 20 patients. *Actinomyces* was isolated and cultured from these patients from exudate obtained bronchoscopically or aspirated from pulmonary abscesses, and in 6 instances taken directly from the lung after pulmonary resection. The finding of *Actinomyces* with such frequency caused considerable concern. Care was exercised to verify the identity of this supposedly pathogenic non-acid-fast anaerobic ray fungus. Sputum is an unreliable source for examinations for fungous infections because of the contamination by the bacterial flora of the mouth. The author discusses the response to conservative and surgical therapy and says that the prognosis depends largely on the severity of the infection. Favorable response occurred with the use of chemotherapeutic drugs and antibiotics, particularly when these were used in conjunction with surgical therapy. In 9 patients healing resulted only after resection of the diseased pulmonary tissue by lobectomy or pneumonectomy.

Treatment of Nasal Diphtheria Carriers.—Medwick and Hallberg report the case of a man, aged 71, who was seen at the Mayo Clinic in June 1947. He complained that he had a bad throat and that he had been found to be a diphtheria carrier in March 1945, after routine culture of material from the nose and throat at a state hospital in which he was employed. Symptoms included a purulent nasal discharge and variable degrees of irritation of the throat for a few years prior to his coming to the clinic. The patient never had been immunized against diphtheria. At the age of 7 years he had had diphtheria. Nasal polyps had been removed, first in 1924 and seven times subsequently. Measures adopted by the patient to alter his status as a carrier of diphtheria included the persistent local application

of various antiseptic agents and sprays for two years, without success. Because of the chronic sinusitis, intranasal surgical treatment combined with the use of penicillin and diphtheria antitoxin was instituted. Convalescence was uneventful. Four successive cultures of material from the nose and throat were submitted during a period of six weeks and all were negative for *Corynebacterium diphtheriae*. The authors conclude that despite the infrequency of the occurrence of diphtheria organisms among nonimmunized patients who have chronic nasal infections, material from the nose should be cultured for diphtheria organisms. Carriers who have been cured should be checked periodically.

Metabolic Study in Cases of Burns.—Keyser studied the daily urinary nitrogen excretion in 20 cases of burns. Only a few showed an average daily nitrogen excretion considerably greater than normal and in many patients it was somewhat low. Nitrogen balances were determined sixteen times in 7 cases. In 5 of these the nitrogen in the exudate from the burned area was measured. The tendency for the nitrogen balance in burned patients to become negative was confirmed, but negative balances seemed to be due to low intake rather than to increased loss of nitrogen. Exudate nitrogen, measured in 10 cases, made up from 2 to 25 per cent of the total nitrogen output (excluding feces). A fall in plasma protein was observed soon after burning in 3 cases in which serial determinations were made over several days. Low plasma protein values were encountered in other cases also. Creatinuria was observed in 3 men with burns of 7 per cent, 15 per cent and 20 per cent of the body surface. Proteinuria was observed in many cases, especially in those with the more extensive burns. Plasma chloride was determined at intervals in a number of cases and correlated with urine chloride. The fall in plasma chloride noted by some earlier investigators was confirmed and is discussed in relation to intravenous plasma therapy. Blood sugar levels (venous blood, Folin-Wu method) after burns of various degrees of severity were measured in 11 cases. In 2 cases hyperglycemia was certain, and in a few others values were perhaps slightly high.

Thyroiditis.—Crile reports on three types of thyroiditis: 27 instances of subacute thyroiditis; 14 of struma lymphomatosa, and 11 of Riedel's struma. The facts that subacute thyroiditis is almost always associated with pain and tenderness and that these symptoms only rarely occur in the other types are evidence against the possibility that subacute thyroiditis represents an early stage of the more chronic processes. The facts that Riedel's struma is more often unilateral, that struma

lymphomatosa usually involves the entire thyroid and that adenomas are frequently present in Riedel's struma but rarely if ever recognized in struma lymphomatosa are further evidence against progress of one lesion to the other. It is possible that subacute thyroiditis is the result of a virus infection. Struma lymphomatosa appears to be a systemic disease, possibly of the deficiency type. Further study of its relationship to achlorhydria, anemia, generalized lymphoid hyperplasia and possibly to vitamin or other deficiencies is indicated. Riedel's thyroiditis appears to be a proliferative form of fibrosis usually centering about a degenerating adenoma. Roentgen irradiation is the treatment of choice for subacute thyroiditis. Thiouracil may be of value. In the rare cases of struma lymphomatosa in which the diagnosis is made before operation roentgen irradiation should be given a trial. If struma lymphomatosa is recognized at the time of operation a conservative resection of both lobes of the thyroid is recommended. The morbidity of radical resection is high. In Riedel's struma roentgen rays are of little value. If the onion-like concentric laminations in the fibrous tissue surrounding the central degenerating adenoma can be found, these avascular planes can be followed by blunt dissection and the core of the lobe shelled out without disturbing its capsule. Symptoms are relieved after this procedure.

Laennec Cirrhosis.—In order to study the histogenesis from the biologic as opposed to the static point of view, Moschowitz examined lesions from the earliest to the most mature phase in serial sections. His studies were made on 75 livers in all stages of cirrhosis. There was evidence that the earliest stage of Laennec cirrhosis is invariably a fatty liver. Transformation of fatty liver to cirrhosis may be caused by interaction of nutritional deficiency and a deficiency of lipotropic factors. If a proper diet is instituted, the fat eventually becomes more or less depleted, but this does not necessarily prevent the cirrhotic process from continuing, at least for a certain period. Under favorable conditions, the cirrhotic process may cease, and the end result is "latent cirrhosis." The first evidence of beginning cirrhosis is an inflammatory reaction, with round cells, monocytes, plasma cells and a few polymorphonuclear leukocytes infiltrating the periportal spaces. This is the exudative phase. The succeeding phase is a productive one and is represented by a fibroblastic transformation. The third phase is the formation of a capillary network in these areas. The further development of these capillaries proceeds according to the laws of Thoma. Many of the capillaries collapse, and the resulting cells evolve into progressive fibrosis and ultimately sclerosis. Other capillaries maintain their integrity and, according to the laws of Thoma, lengthen and enlarge and serve as the main blood supply of the granulomatous and fibrous strands. Serial section shows that these vessels communicate with the portal veins. No evidence is found of an arterial supply of these strands. This further evolution is similar to that in the embryo and in granulation tissue. These granulomatous areas at first penetrate into the interlobular septal spaces or into the lobule and unite with similar adjacent projections from other portal spaces. Often they unite with projections from the hepatic veins, partially converting the blood supply of the liver as in an Eck fistula. These have been termed bivenous strands. This distribution forms the typical pattern in Laennec cirrhosis. The progressive sclerosis and its elastic transformation convert the liver from a

hypertrophic to an atrophic one. In this interpretation the connective tissue structure is the result of the multipotential properties of the cells of the adult mesenchyma, which maintain in a large measure their embryonic potentialities.

Splenectomy During Childhood.—Splenectomy was performed on 55 children at the Surgical Department of Ohio State University College between 1933 and 1946. Van Buren and Curtis cite following indications for the operation: congenital hemolytic icterus, thrombopenic purpura and the Banti syndrome. Splenectomy was also performed for splenic panhematocytopenia, traumatic rupture, sickle cell anemia, hypoplastic anemia, Gaucher's disease and pseudohemophilia. The age of the infant with congenital hemolytic icterus should be no contraindication to splenectomy. The youngest patient in this group was 30 days old. There was 1 fatality in 20 children subjected to splenectomy on account of congenital hemolytic icterus. As to the indications in thrombopenic purpura, the authors feel that splenectomy is not contraindicated even in the presence of an acute crisis, provided adequate preoperative blood transfusions are given. Delay in removing the spleen may result in a fatality. Two of the 22 patients with thrombopenic purpura were treated with preliminary supportive measures, but despite medical management the condition of the children became progressively worse. Emergency splenectomy in both instances proved efficacious. The remaining 20 were operated on during the interval of quiescence. There was 1 fatality after splenectomy. In the 7 patients in whom the condition was diagnosed as Banti's syndrome, the changes observed in the spleen after splenectomy were compatible with those commonly found. One of the 7 patients with Banti's syndrome died after splenectomy. Accessory spleens were found in 2 of the 22 children with thrombopenic purpura and in 13 of the 20 children with congenital hemolytic icterus. Failure to remove the accessory spleen at the time of splenectomy may result in a recurrence.

Ligation of Splenic Artery in Portal Hypertension.—According to Everson and Cole the portacaval shunt type of operation appears to offer the greatest promise for the relief of the distressing effects of portal hypertension. It is, however, an operation of considerable magnitude, and places a tremendous additional load on an already overtaxed patient. The procedure which they emphasize for poor risk patients is ligation of the splenic artery. This operation is a relatively minor intervention when compared with splenectomy or portacaval shunt. The procedure is not new, but it has not been widely used. After ligation of the splenic artery 1 of the 3 patients operated on showed immediate improvement, which has persisted up to date (one year after operation). The second patient is alive almost three years since the operation. Ascites has not improved appreciably, but the patient reports subjective improvement. This, together with the length of the survival period, suggests that the ligation of the splenic artery was of some benefit. The third patient died four months after the

ligation. Experience with omentopexy performed in their cases and the work of Cates indicate that the favorable results are not due to this procedure. Ligation of the splenic artery will not replace portacaval shunt in the treatment of portal hypertension. It is indicated in patients who could not tolerate the more extensive procedure. Even though there is an appreciable decrease in the size of the spleen after ligation, there was no evidence of necrosis.

Phlebothrombosis Associated with Carcinomas of Pancreas.—Jennings and Russell add 2 cases to the list of malignant pancreatic tumors associated with a thrombotic tendency. The pathologic study of the two patients demonstrated remarkably similar pathologic changes. In each there was a carcinoma of the tail or the body of the pancreas in which the tumor cells were producing intracellular and extracellular substance. One of the tumors was producing an abundant amount of basophilic-staining mucus, while in the other only a small amount of intracellular and extracellular substance was demonstrated. There was associated phlebothrombosis involving both the portal and the systemic venous systems in each case. The most reasonable explanation for the phlebothrombosis was some alteration of the blood-clotting mechanism. These 2 cases are examples of a characteristic syndrome, in which a high incidence of phlebothrombosis is associated with carcinomas arising in the tail or the body of the pancreas. Specific knowledge concerning the relationship of disturbance in the mechanism of blood coagulation to the syndrome under consideration might prove helpful in the establishment of an early diagnosis. To date, no clearcut clinical differentiation has been made between multiple thrombophlebitis ("migrating phlebitis") and multiple phlebothrombosis. Once these two conditions can be established as separate clinical entities, it is possible that a definite clue may be had to the existence of mucinous carcinoma situated in the pancreas, stomach or lung, the odds greatly favoring the first-mentioned organ. Such evidence may well constitute an indication for abdominal exploration and possible cure of the disease.

Surgical Treatment of Psychoses.—Liebert and Davis review the results obtained with prefrontal lobotomy in 38 cases. Twenty-five patients improved and of the improved patients 12 were discharged from the institution. Thirteen patients remained unimproved. All of the patients subjected to prefrontal lobotomy had been ill for many years and constituted a severe behavior problem in a mental institution. Untoward effects of the operation as incontinence of urine, epileptic seizures and lack of initiative following the operation, must be expected in some cases.

Insulin and the Degenerative Changes in Diabetes Mellitus.—Hedges points out that more attention must be given to such early degenerative changes in diabetes mellitus as albuminuria, moderate hypertension and beginning retinitis, rather than to the development of arteriosclerosis in the extremi-

ties, if one is to prolong the life of diabetic persons and protect them against complications. At present little is done except attempting to control the blood sugar through the use of diet and insulin, and, while insulin may control glycemia, it does not check the development of degenerative lesions. More information is required on the need for additional insulin in diabetic patients when infection is present and more attention must be given to the acceleration of degenerative processes in diabetic patients, for at present there is no treatment for these.

Sublingual Methyl Testosterone for Immaturity in Boys.—Harding says that in boys with unusually small genitalia a neurosis may be caused by the fear of abnormality. Methyl testosterone enlarges all parts of the male genitalia before or during puberty. When small doses of it are given, it does not initiate the onset of puberty in a child too young for the occurrence. Methyl testosterone was administered in small daily doses to a selected group of 58 boys between the ages of 7 and 15 years. Tablets of methyl testosterone were held under the tongue or between the teeth and the check and were allowed

to dissolve slowly. They each contained 5.0 mg. of material and were cut in half or in fourths for the 2.5 mg. or 1.2 mg. doses. The total daily dose varied between 0.6 and 10 mg. Treatment was continued for two to twenty months. Genital development was considered satisfactory in all patients taking methyl testosterone. Satisfactory development of primary and secondary sex characteristics occurred. In some patients there was an increase in weight and production of greater muscular strength. The average rate of growth as determined by height was increased to 3.2 inches (8.1 cm.) per year. The neuroses due to the presence of unusually small genitalia were cured. There was less emotional immaturity.

Nontuberculous Pulmonary Calcification.—Biggs and Rigby point out that calcium deposits in the lungs or at their hilum were always considered to be pathognomonic of tuberculosis. In recent years evidence has accumulated that there are other causes of pulmonary calcification. The authors obtained consistently negative tuberculin reactions in 14 children who had calcium deposits in the chest. One child had Boeck's sarcoid involving the lungs without cough. Acid-fast bacilli were demonstrated by direct smear in the secretion aspirated through the bronchoscope in this 1 patient only. The authors regard bronchoscopic methods of study in questionable cases of tuberculosis as valuable. A thorough clinical study, including bronchoscopy and bacteriologic study of the aspirated secretions, failed to produce evidence that these children had or had had a tuberculous infection. Eight of these 13 patients with pulmonary calcification had some change in the mucous membrane at the bifurcation or in the main bronchi. Eight had a history of frequent colds or persistent coughs. Twelve of the 13 were given cutaneous tests with histoplasmin. Six of the 12 gave an immediate reaction to histoplasmin. On the basis of these observations and of reports in the literature the authors conclude that pulmonary calcification may be caused by factors other than pulmonary tuberculosis. It has not been definitely determined what these factors are, but there is suggestive evidence that a mild subclinical histoplasmosis may be one of them. Ordinary recurrent infections of the respiratory tract may be another.

BAL in Experimental Lead Poisoning.—The experiments described by Germuth and Eagle proved that BAL (2,3-dimercaptopropanol) failed to protect rabbits that had been poisoned with lead acetate. At times it actually accelerated the toxic effects of lead acetate in rabbits. The experimental lead poisoning produced in rabbits by either the subcutaneous or the intravenous injection of lead acetate differs so materially from that seen in man, with respect to the route of administration, the chemical form of the lead, the chronicity of the intoxication and the organs affected, that the results obtained with BAL in these experimental animals have no necessary significance with respect to its possible therapeutic activity in man. Despite the present complete failure of BAL to detoxify lead in rabbits, its effect on the urinary excretion of lead was so striking as perhaps to justify its cautious therapeutic trial in human cases. For two hours after a single injection of BAL at 20 mg. per kilogram of weight, the urinary excretion of lead increased

eleven to forty fold in animals with a subcutaneous depot, and three to seven fold in animals injected intravenously. This favorable effect on the excretion of lead lasted for approximately four hours after a single injection of BAL.

Penicillin in Weil's Disease.—Moser reports 2 men, aged 30 and 27, respectively, with symptoms of Weil's disease and a history of probable contact with rats while swimming and camping. Treatment with sulfadiazine had failed; penicillin in doses of 50,000 units every two hours was given for 12 doses, and after that at somewhat longer intervals. These cases suggest that penicillin is effective if given during the bacteremic phase. There is no way of making the diagnosis except by finding the leptospirae in blood smears during the first week. This is difficult for the ordinary laboratory technician. If the physician withholds the therapy until after the diagnosis has been made, the effectiveness of penicillin becomes progressively diminished and the disease may be fatal. The reason that penicillin loses its effectiveness after the onset of jaundice or nephritis is perhaps that the spirochetes take up residence in all the organs of the body and high therapeutic concentrations of penicillin cannot reach them. The author bases his belief that penicillin produced the clinical cure in the 2 cases on the definite improvement in the temperature curve within twenty-four hours after the beginning of penicillin therapy; the moderate Herxheimer reactions which the patients demonstrated after their second injection of penicillin, and the general clinical improvement. The failure of complete clinical recovery in the first case as manifested by fatigability and headaches suggests the existence of low grade hepatitis, which took six months of good diet to clear up.

Mercurial Diuretics in Paroxysmal Nocturnal Dyspnea.—Sokolov presents observations on 47 patients with evidence of left ventricular failure and, more particularly, paroxysmal nocturnal dyspnea. The treatment of the individual attack of paroxysmal dyspnea was along conventional lines. Morphine in $\frac{1}{4}$ to $\frac{1}{2}$ grain (16 to 32 mg.) doses was given hypodermically, usually in conjunction with $\frac{1}{100}$ grain (0.6 mg.) of atropine. When indicated, oxygen via tent was also supplied. If the patient had not been previously digitalized, rapid digitalization was induced by giving 1.2 mg. of digitoxin in twelve hours, to be followed by a daily maintenance dose of 0.1 to 0.2 mg. Bed rest was enforced for a varying length of time. If the patient was overweight, a low caloric diet was prescribed. Regardless of the patient's weight, a salt-poor regimen was instituted.

Many of these patients ultimately required more energetic diuresis, so that mercurial diuresis was made an integral part of the treatment in all cases in which no contraindication existed. Acidifying agents, such as ammonium chloride, enhance the diuretic effect of the mercurials. The mercurial diuretic used was meralluride. The first dose of meralluride is 1 cc. intravenously. This is followed in four days by a 2 cc. dose. Thereafter injections of 2 cc. are given once a week until the patient is considered stabilized. At this point the interval between injections is lengthened as much as possible. Mercurials should not be given in the presence of severe renal disease, in severely dehydrated patients or those with depleted serum chlorides, in the moribund, in the presence of shock associated with recent myocardial infarction, in patients having previously exhibited idiosyncrasy to the drug and in the presence of large amounts of digitalis-containing edema fluid. The author emphasizes that, although this treatment is not new, its value has been inadequately emphasized.

Carcinoma of Stomach.—Welch and Allen review observations on patients with carcinoma of the stomach admitted to the Massachusetts General Hospital during the ten year period 1937 to 1946. Comparison with earlier reports shows that the delay before treatment has remained unchanged, averaging five months. A more aggressive attitude toward gastric ulcer has increased the recognition of early cancer of the stomach. The introduction of a transthoracic approach and the wider use of total abdominal gastrectomy have increased the number of cases available for resection. The mortality for gastric resections for cancer has dropped to a present level of 17 per cent for the entire series and to 11 per cent in the last five year period. The mortality for subtotal resections in which all gross disease is removed has been 3 per cent in the last five year period. Meanwhile, the number of patients not operated on has declined, so that 75 per cent have an operation. Fifty per cent of the total have a gastrectomy, either subtotal or total. The best palliative operation, if gross disease cannot be removed, is subtotal gastrectomy. The five year survival rate is now 7 per cent of the entire group that enters the hospital. The most fruitful method now available to increase the number of cures of cancer of the stomach is to reduce the delay from onset of symptoms to surgical intervention.

- Appearance of "Minimus" Type Diphtheria in Utah. T. W. Galbraith, R. S. Fraser and E. H. Bramhall.—p. 577.

Dental Effects of Fluorinated Waters.—The study reported by Klein is based on examination of nearly 2,000 children residing in New Jersey and more than 6,000 children of Hagerstown, Md. Of the New Jersey children ranging in

age from 5 to 19 years, 874 were born and reared in a fluoride area, 725 moved into the fluoride area at various ages subsequent to birth in places outside the fluoride areas and 340 children were lifetime residents of the nonfluoride area. The depressant effect of fluorides on caries may be approximately of equal potential for all the different types of teeth. Because of the different gradients in the characteristic or expected caries susceptibilities of the different teeth, the resultant effect may be a variation in the per cent reduction of caries among the different teeth. Consideration of the differences in caries reduction among the different teeth leads to the view that the differential effects are perhaps related to basic differences in the characteristic susceptibilities of the different teeth. Even after prenatal exposure and a postnatal residence of fifteen to nineteen years in a fluoride environment, caries attack is reduced only by about a third of normal expectation in the lower molar teeth of lifetime residents. Although this is a significant reduction, particularly from the point of view of the total need for dental service in the population, it is necessary to recognize that approximately two thirds of the treatment problem for caries still arises among molars in the fluoride area.

Vagotomy in Peptic Ulcer.—Meyer and his associates report 35 cases in which previous medical or surgical management had failed to give relief from ulcer pain. There were 16 instances of previous perforation. Nineteen patients had had previous bleeding. Repeated attacks of severe epigastric pain were present in 31 of the 35 patients, and in 12 the pain was intractable. Duodenal ulcer was present in 26 patients, marginal ulcer in 7 patients; 1 patient had a gastrojejunal colic fistula and 1 had a prepyloric ulcer. The transthoracic approach was employed in the first 9 cases and the transabdominal approach in the remaining 26. The latter is now preferred, because of several advantages. All patients had immediate relief from ulcer pain. Thirty-one of the 35 are leading an

unrestricted life for the first time in many years. Dietary and medical treatment has been completely eliminated. The majority of patients noted a change in the bowel habit. They had one or two soft bowel movements a day, whereas preoperatively almost every patient gave a history of constipation. Thirty-one patients expressed themselves as being well satisfied with the results. One patient died because of uremia and nephrosis which followed a blood transfusion. Recurrence of ulcer symptoms with positive roentgen evidence of peptic ulcer occurred in 4 cases. The symptoms of cardiospasm were noted in 3 patients, but were spontaneously relieved. The most frequent and disturbing complication was gastric retention and distention, but this has been controlled. The permanency of the altered gastric function following a complete vagotomy is not yet certain, and little is known of the effect of vagotomy on the other organs innervated by the vagi. The use of vagotomy should be limited until more information is available. Complete vagotomy is the method of choice in marginal ulcer following gastric resection.

Discrepancies in Myelography.—Scoville and his associates had gained the impression that myelography yields equivocal findings in at least 25 per cent of the cases. This is at variance with published statistics. They analyze 200 consecutive cases in which patients were subjected to pantopaque myelography and operation for a lumbar ruptured intervertebral disk at the Cushing General Hospital. Four cases of lumbar spinal tumors were excluded from the statistics. Ruptured disks were found in 173 of the remaining 196 patients operated on. Findings in the 23 other cases were swollen nerve roots, adhesions, bony ridges, one fractured facet and, more commonly, nothing. Double disks were found in 11 per cent. Over-all errors occurred in 65 out of 196 cases. In order to rule out the personal equation from these diagnostic errors, the authors made a comparison with two surveys made by other investigators. Clinical evidence of a ruptured disk is more important than is myelographic evidence. A positive myelogram is more important than a negative one. A normal myelogram in the face of clinical evidence of a ruptured disk will be wrong three out of four times. Myelography fails to rule out the presence of a laterally placed lumbosacral disk. When myelography is used as the sole diagnostic criterion, the over-all error is in the neighborhood of 25 to 35 per cent in contrast to the 6 to 8 per cent cited in the literature. The authors will continue to use myelography routinely on all persons suspected of having ruptured disks, but will tend to discount all normal myelograms if contradicted by the clinical findings.

Correction of Hypoproteinemia by Plasma and Blood.—Allen and his associates report a study of 9 hypoproteinemic patients who were given large volumes of plasma in an endeavor to elevate the plasma proteins. Whole blood was sometimes given to correct anemia, but in all but 2 patients the greatest source of parenteral protein was plasma. The amounts of plasma, usually given daily, were large as measured by current practice, but the amount of nitrogen given by this method was less than that advocated when protein hydrolysates are used for this purpose. The increase in the plasma protein concentration was rapid after these quantities of plasma and blood were given. Normal values were usually established within five to seven days. Nitrogen balance studies and plasma volume changes in 6 of these patients showed that most of the transfused plasma probably left the blood stream within a day or two. That which could not be accounted for on the basis of an increase of total circulating plasma protein may possibly have been recast as tissue protein, since there was little, if any, evidence of a latent increased nitrogen excretion. Larger amounts of plasma and blood were required to elevate the plasma protein concentration in the more severely starved patient than in the better nourished one, even though the plasma protein concentrations were reduced to similar levels in both groups. This work suggests that the fear of over-transfusion is unwarranted except when the cardiovascular reserve is reduced. It emphasizes the wisdom of using blood in some patients in place of plasma because of the gain in oxygen-carrying cells and the possible utilization of hemoglobin to form tissue proteins.

Tuberculosis of Larynx.—According to Brahy, tuberculosis of the larynx is to be considered as a complication of pulmonary tuberculosis exclusively, because primary tuberculous lesions of the larynx have not been demonstrated and tuberculosis of the larynx has not been reported in association with tuberculosis of bones, peritoneum, meninges or eyes. For several years the incidence of advanced cases of pulmonary tuberculosis decreased as the result of a successful campaign against this disease. It also explains the reduced number of cases with laryngeal lesions, which, however, may be observed in two thirds of those cases of pulmonary tuberculosis which cannot be controlled. The age groups between 25 and 40 years are affected most frequently. Laryngeal lesions are observed three times more often in men than in women. One hundred patients with pulmonary tuberculosis, many of whom presented laryngeal lesions, were treated with streptomycin at the hospital of the Sacré-Coeur in Cartierville, Montreal. Five milligrams of the drug was administered by intramuscular route every morning and evening for three weeks. In 1 male patient aged 40 with bilateral pulmonary cavities and considerable involvement of the larynx, theodynophagia subsided completely after the second week of this treatment, and his body weight was increased 25 pounds (11.3 Kg.) after three weeks of treatment. The left half of the larynx was practically healed, while diffuse edema of the right half was still present. The cavity of the right lung did not appear cleared on roentgenologic examination, while the aspect of the left lung was satisfactory. Although not all the other patients were improved to the same degree, it is believed that streptomycin has a favorable effect on the ulcerations of the larynx, leaving a uniform and smooth mucosa. This effect is more pronounced with extensive than with small lesions. The present tendency is to continue the treatment with streptomycin for a period of one hundred and twenty days.

Penicillin and Sulfathiazole in Typhoid.—Bevan and associates point out that considerable interest was aroused when Bigger in 1946 found that typhoid bacilli are effectively inhibited in the test tube by the combined action of penicillin and sulfathiazole. A typhoid outbreak in which the vehicle of infection was ice cream infected by a urinary carrier offered an opportunity for a trial of the combined penicillin-sulfathiazole treatment. The 39 patients who received courses of combined penicillin and sulfathiazole, similar to those found effective by McSweeney in 1946, did not show the speedy disappearance of toxemia and subsidence of pyrexia described by McSweeney. Three small groups of patients treated with penicillin-sulfa-

thiazole were compared with three untreated control groups. There was no evidence of an appreciable clinical effect of the drug treatment. There were no fatalities in the largest group of 25 treated patients, but 5 of the patients whose condition caused the greatest anxiety had been given Felix's "Vi+O" antityphoid serum. A considerable proportion of patients yielded positive blood cultures shortly after completion of their courses of penicillin-sulfathiazole treatment. Fecal excretion of typhoid bacilli during convalescence was not shorter in the treated groups than in the controls. The typhoid strain responsible for the reported outbreak was not more resistant to the action of penicillin and sulfathiazole than were four other strains with which it was compared in tests in vitro. The authors warn against the indiscriminate use of penicillin and sulfathiazole in the treatment of typhoid.

Measured Radical Gastrectomy.—In this review of 505 operations for peptic ulcer Visick asserts that the essential point of technic of a measured radical gastrectomy is division of all but one of the vasa brevia and all branches of the left gastro-epiploic artery. This makes it possible to leave a small devascularized gastric remnant $1\frac{1}{2}$ inches (3.8 cm.) and 3 inches (7.6 cm.) long on the lesser and greater curvatures, respectively. A measured radical gastrectomy differs from a conventional three-quarters resection in three respects: (1) the area of stomach which remains can be measured and controlled with accuracy; (2) the gastric remnant is extensively devascularized, and (3) in 98 per cent of cases permanent relative achlorhydria is produced. The operative mortality for the last 430 gastrectomies was 3.7 per cent. A penetrating ulcer caused twice the operative mortality of a nonpenetrating ulcer. If the history was over five years, the operative mortality was increased two and one-half times. One patient among 155 under the age of 40 died. The operative mortality among patients aged 40 to 49 was 5 per cent; aged 50 to 59, it was 5.8 per cent, and 60 and over, 7.1 per cent. Of the 430 patients examined from six months to twelve years after operation 95.1 per cent showed satisfactory results. The year by year continuous follow-up indicates that results improve with time. The proportion of patients who are free of symptoms at six months (47 per cent) rises to 63 per cent at forty-two months after operation. Women were more liable to have minor symptoms resulting from operation. In spite of wide resection macrocytic anemia has not been discovered. No ulcer recurred later than eighteen months after gastrectomy.

*Four Cases of Carditis Occurring in Children and Associated with Administration of a Foreign Serum. Joan Storey.—p. 337.

Carditis Following Administration of Foreign Serum.—According to Storey there is a close analogy between certain of the symptoms of rheumatic fever and those of serum sickness. Polyarthritides, fever, rashes and lymph node enlargement may occur in both. In view of the present theory that rheumatic fever may be akin to an allergic reaction, a hypersensitivity to the hemolytic streptococcus group A, the author pursued the analogy of the 2 cases more closely. The greatest danger in rheumatic fever is in the damage done to the heart, and this is not ordinarily a feature of serum sickness. The 4 cases cited by the author have in common the development of polyarthritides, fever, raised blood sedimentation rate and carditis following the injection of a foreign serum. In the last 3 cases serum sickness occurred in the interval between the injection of the serum and the discovery of carditis. It is well within the bounds of possibility that these children suffered an attack of rheumatic fever in which the "Phase 1" infection passed unnoticed and that the serum sickness, which developed more quickly than usual after injection of serum, was purely coincidental. This is especially so in view of the fact that the administration of tetanus antiserum is a fairly common procedure and that these 4 cases were selected from over a thousand histories of rheumatic fever investigated. A second explanation

is that given by Wadsworth and Brown, who, in discussing their case of carditis, pointed out that there is much to favor the assumption that carditis may have been reactivation of sub-clinical rheumatic fever by protein shock.

Pneumonokoniosis in Coal Miners.—Nisbet describes how the "Special Pneumonokoniosis Board of New South Wales" operates, and attempts to evaluate the cause of fibrosis of the lung tissue on the basis of nearly fifteen years' experience as radiologist to this special board. It is unfortunate that the two different terms "reticulosis" and "nodular fibrosis" are used by separate authorities to mean the same thing, anthracosis. Silica is the cause of the disability in coal miners as well as in other miners. Miners working in a pit with the greater content of silica in the coal or seam, and therefore in the dust, will show the greater percentage of cases of pulmonary disease. The quartz miner may contract silicosis in five to seven years; the metal worker without proper precautions in under ten years; the asbestos worker, the flour miller and others take longer still. The soft coal miner must work at least twenty years before manifestations of anthracosis occur. The incidence among coal miners in New South Wales of superadded tuberculosis appears far less than that among the remainder of the population. The total incidence of men with incapacitating pulmonary fibrosis due to dust was 4.90 per thousand colliery employees per year.

*Serious Limitations and Erroneous Indications of Biopsy in Diagnosis of Tumors of Bone. J. F. Brailsford.—p. 225.
Surgery in Treatment of Rheumatoid Arthritis and Ankylosing Spondylitis. W. A. Law.—p. 251.

Limitations of Biopsy in Bone Tumor.—Brailsford shows that it is erroneous to suppose that biopsy will permit the surgeon to establish whether a bone tumor is benign or malignant, when clinical and roentgenographic observations by competent observers have failed to clarify this question. Actually biopsy may add conflicting evidence which will delay the accurate diagnosis. Ultimate resolution of a bone tumor which had clinical, roentgenographic and even histologic appearances of malignancy is the best evidence of simplicity. In view of the not uncommon occurrence of such cases, it is unjustifiable to record lesions as "fully proved" malignant tumors if amputation results in cure. A malignant bone tumor appears to indicate a local expression of a constitutional disturbance, which may disappear when the patient is given the essential corrective; for in spite of the earliest amputation similar lesions may develop at any time after, even with twenty years' symptomless interval. Yet primary lesions and the multiple associated lesions which have the features of metastases may resolve completely or sufficiently to permit of the average duration of symptomless normal life. The response of carcinomatous metastases from some primary carcinomas in the breast or prostate to diethylstilbestrol gives hope that some such hormone will be found to cure sarcoma. In the investigation of bone tumor particular attention must be paid to hereditary dysplasia or dystrophy, the possibility of vitamin deficiency, endocrine or blood disorder, infection or trauma. If the roentgenographic appearances indicate a simple lesion the appropriate treatment should be given. If the lesion has the roentgenographic features which suggest malignancy the only treatment which present imperfect knowledge dictates is amputation. This is an irrevocable procedure, the success of which cannot be predetermined. As the roentgenographic appearances can be closely mimicked by inflammatory or deficiency and other disorders, it would be reasonable in any doubtful case to give a course of appropriate

medication, and if this fails, a course of high voltage roentgen therapy. Even when it is established beyond doubt that the tumor is malignant and amputation is decided on, there appears to be some justification in preceding this with a full sarcoma dose of roentgen rays.

Peptic Ulcer of Esophagus.—Allison shows that for a long time peptic ulceration of the lower part of the esophagus did not receive proper attention, but more accurate observation in recent years has led to more frequent diagnosis of these ulcers. Seventy-four instances of this condition have been studied in the thoracic surgical unit at the General Infirmary at Leeds. Dysphagia always more marked for solid foods than for liquids, was the symptom that brought most of these patients to the hospital. Dyspepsia was present in about three fourths of the patients. It occurred in 1 of 3 forms: (1) high epigastric discomfort associated with high acid secretion and related to disturbances of gastric motility; (2) burning pain behind the sternum caused by acid bathing the lower end of the inflamed esophagus, and (3) a more boring type of pain passing into the back between the shoulder blades and often made worse by flexion of the spine. Diaphragmatic defect is the most important etiologic factor. Heterotopic gastric mucosa in the esophagus accounts for few. Congenitally short esophagus occurs but rarely; it has not been seen in this series. Defects in the diaphragm allow herniation of the cardia into the mediastinum and so render ineffective the mechanism for keeping acid out of the esophagus. These hernias may be congenital (congenital short esophagus), infantile or acquired. There are 7 examples in infants in the present series. The acquired group includes 4 patients in whom ulceration followed gastroesophageal anastomosis after excision of carcinoma of the cardia.

*Significance of Tuberculin Sensitivity. I. Bluhm.—p. 73.
Mass X-ray and Health Propaganda. Jocelyn Goldsborough.—p. 82.
BCG Vaccination of Nurses. J. Heimbeck.—p. 84.

Significance of Tuberculin Sensitivity.—In order to find out whether there exists a connection between the size of the tuberculin reaction and the tuberculous infection, Bluhm studied a series of healthy persons and of persons with tuberculosis. The investigation has been carried out at the Central Dispensary of Stockholm. He employed dosages of 0.05 mg. of old tuberculin. The sensitivity has been evaluated by measuring the length and breadth of the red papule. In persons without manifest tuberculosis, who live in a milieu in which tubercle bacilli are to be found, tuberculin sensitivity is usually increased. If the source of infection is removed, the reaction decreases. The cause of hypersensitivity is probably a continuous exposure to tubercle bacilli. Thus if persons without tuberculosis prove hypersensitive, the environment should be investigated. In persons with manifest tuberculosis there is a certain regularity in the fluctuation of the tuberculin reaction. In persons with erythema nodosum and primary pulmonary tuberculosis tuberculin sensitivity is usually much increased. Sensitivity seems to be maximum in an early phase of the infection. Tuberculin sensitivity shows a gradual decrease on repeated testing. In patients with exudative pleurisy the reaction is comparatively low. In pulmonary tuberculosis sensitivity is stronger in the exudative than in the productive cases. In healed tuberculosis exposure to tuberculosis may bring about an increase in the reaction even though no fresh lesions appear. In pulmonary tuberculosis with cavities, in which the lesions are productive or exudative-productive, sensitivity is also low. It seems that the variation in sensitivity does not depend so much on whether the disease is extensive, progressive or regressive as on whether it is in an exudative or a productive phase.

- Resorption of Penicillin After Inhalation. P. Dragsted and M. Schwartz.—p. 45.

Porphyrin in Urine as First Symptom of Lead Poisoning.—De Langen and ten Berg found that increased excretion of porphyrin in the urine was an early sign of lead poisoning among the population of a district in which the water contained comparatively large quantities of lead. The semiquantitative method found useful in these investigations requires 20 cc. of urine, to which are added some drops of glacial acetic acid and 2 cc. of ether. The test tube is shaken and is examined under ultraviolet light, in which the layer of ether fluoresces. In the presence of a normal porphyrin content of the urine the fluorescence is light blue to green, but in the presence of increased porphyrin content gradually deepening red fluorescence appears as the porphyrin content increases. In case of an equivocal result a quantitative method can be employed. This method is also described. The aforementioned method appeared to be more reliable for detecting the first signs of lead poisoning than the basophile granulation of the erythrocytes. This was proved (1) by a comparative examination of both criteria in 87 persons who all had more or less high excretion of porphyrin due to intake of lead and (2) by an experimental examination of normal persons taking predetermined quantities of lead. The authors are convinced that in the routine control of workers in the industries using lead the semiquantitative porphyrin method is much better than looking for basophile granulation.

- Roentgen Examination in Acute Dilatation of Stomach. J. F. Dahl.—p. 237.
- Treatment of Keloids at Radiumhemmet 1921-1941. F. Jacobsson.—p. 251.

Influence of Roentgen Castration in Carcinoma of Breast.—Thayssen states that at the Radium Center in Copenhagen several hundred patients were treated between 1934 and 1943 for cancer of the breast with metastases. Of these, 99 were given local treatment of both the primary tumor and the metastases, and underwent roentgen castration some time after the appearance of the metastases, whereas the others got only local roentgen treatment. It was found that 40 per cent of the castrated patients were still living two years after the appearance of the metastases as against only 11 per cent of 100 controls. Of 74 patients given roentgen treatment before or after operation and castrated, 28 per cent were alive five years after the operation, as against 8 per cent of the controls. On the basis of 79 urinalyses for gonadotropin and estrogen it is shown that the castration may have a highly beneficent effect even in cases in which the estrogen output was low also before the castration.

Protrusion of Acetabulum in Labor.—Petersen says that although it had been suggested many years ago that protrusion of the acetabulum could be the cause of dystocia, no case seems to have been reported until one was observed at the author's hospital in 1944. The patient was a primipara, aged 32, in whom delivery was protracted (about forty-five hours) and in whom both the clinical and the roentgenologic examinations, as well as the pressure traces on the skull of the child, make it probable that the protraction was due to protrusion of the patient's acetabulum. The chief feature of protrusion of the acetabulum or Otto's disease is an abnormally strong dome-shaped projection of the floor of the acetabulum into the small pelvis. The author discusses the cause of the disease.

- *Isoimmunization of Mother for Factor of "A" Blood Group of Fetus. R. Medina Aguilar.—p. 49.

Isoimmunization of Mother from Fetus of A Blood Group.—The subject of this report, a woman 37 years of age, had had 9 normal children and 3 abortions. Her blood was of group B, Rh positive and MN positive. There was no syphilis in the family. In the course of the thirteenth pregnancy she contracted moderate diabetes and moderate hypochromic anemia. Her blood serum agglutinated blood of the A group, both Rh positive and Rh negative. It did not agglutinate blood of either B or O groups. After inactivation it hemolyzed blood serum of the A blood group. The father's blood was of group A, Rh positive and also MN positive. The children belong to A, AB or O blood groups. All are Rh positive. The patient was brought to the hospital with acute hemorrhage from placenta previa with a dead fetus whose blood was of group A, Rh positive and MN positive. The fetus presented hepatomegaly, splenomegaly and blood containing 84 per cent erythroblasts, the majority of which were of the Lendorff type. The liver and the spleen contained large numbers of erythroblastic nests which greatly damaged the structure of the organs. The findings in the fetus clarified the isoimmunization of the mother of the B blood group by a fetus of the A blood group, notwithstanding the fact that both the mother's and the fetus's blood were Rh positive and also MN positive.

- *Banti's Complex of Symptoms and Its Relations to Occult Malaria During Childhood. A. Eckstein.—p. 113.
- Tropical Aspects of Pathology of Liver in Pediatrics. E. Stransky and F. Daus Lawas.—p. 131.
- Synechia Vulvae in Children. K. Vesely.—p. 151.

Banti's Disease and Occult Malaria During Childhood.—Eckstein of Ankara believes that in the presence of disorders that show splenomegaly, degeneration of splenic tissue and its replacement by connective tissue, Banti's syndrome will have to be considered, if malaria, kala-azar, cirrhosis, glycogen disease, Niemann-Pick's disease and the like can be ruled out. Further advancement in diagnostic procedures will probably limit the concept of Banti's disease more and more and replace its diagnosis by one of the aforementioned group. The author cites a case in which repeated examinations of the blood and of the sternal and splenic punctates and observation of the temperature justified the diagnosis of Banti's disease after all other possibilities, particularly malaria and kala-azar, had been ruled out. When the spleen, which weighed $3\frac{1}{2}$ Kg. (7 pounds, 11 ounces), was removed it showed histologically only degeneration with proliferation of the connective tissue, while the characteristic signs of malaria (plasmodia and pigment) were absent. Immediately after the operation the typical picture of tertian malaria (type of temperature curve, tertian ring forms) developed. There existed in this case an occult form of malaria which had presented the picture of "Banti's disease." In spite of the splenectomy there were no complications, and the patient was eventually cured after several relapses. The case corroborates earlier impressions that malaria in patients without a spleen is not necessarily extremely serious or even fatal as some authors have claimed. The author feels that splenectomy is justified in similar cases.

Arch. Hosp. Clin. Niños Roberto del Rio, Santiago**15:151-208 (Dec.) 1947. Partial Index**

- *Leukemias in Infancy. A. Costa.—p. 158.

Leukemia in Infants and Children.—Costa reports observations on 37 leukemic patients, between the ages of 6 months and 10 years. There were 25 boys and 12 girls. Leukemia was of the acute type in 29 patients, of the chronic myeloid type in 5 and monocytic in 1. The youngest patient in the group with acute leukemia was 6 months old. Acute leukemia appears to be frequent in infants and in young children. It represents 80 per cent of the total number of cases of infantile leukemia. In acute leukemia of infants and children there are remissions

during which the leukemic changes of the blood are lacking. This fact makes the myelogram of great diagnostic importance. The duration of the disease is short, especially in infants and young children. The clinical and hematologic picture of chronic myeloid leukemia in infants and children is similar to that of adults. The cases of monocytic leukemia observed by the author were all of the Naegeli type and of short course.

*Electrocardiogram and Patent Ductus Botalli. W. den Boer.—p. 698.
Phrenic Shoulder Pain. G. J. Smelt.—p. 706.

Electrocardiogram and Open Ductus Botalli.—According to den Boer 3 children with symptoms of patent ductus arteriosus (Botalli) were seen during the last year at the clinic in Utrecht. Deviation in the electrocardiogram of the axis to the left may occur, but a decided deviation to the right makes it almost certain that the open ductus is complicated by other defects such as pulmonary stenosis, or that a patent ductus arteriosus does not exist. Deviation of the axis to the right is a contraindication to operative treatment. The electrocardiographic examination is of great value in the differentiation of patent ductus arteriosus with and without complications. It will help prevent operations where they are not advisable and will also prevent bringing an otherwise valuable operation into discredit.

Chemotherapy in Rheumatic Polyarthrititis. N. Svartz.—p. 299.
*Gold Treatment in Chronic Polyarthrititis. F. Sundelin.—p. 303.
*Chronic Polyarthrititis in Children and Gold Treatment. B. S. V. Bille.—p. 307.
Myasthenia. S. Refsum.—p. 311.

Gold Treatment in Chronic Polyarthrititis.—Reactions or complications were seen in 50 per cent of 2,817 courses of treatment in 1,904 cases of polyarthrititis treated with gold in the last five years; only 4.5 per cent of the complications were grave and led to the interruption of the treatment. Seven cases were fatal. On completion of treatment fully 90 per cent of the patients were subjectively and objectively improved both as to local symptoms and general condition. Preliminary report on late results shows that of 300 patients given treatment with colloidal gold completed at least three years ago 273 continue fully or partly able to work. Because of its effectiveness, treatment with colloidal gold occupies a special place among the therapeutic means tried to date in chronic polyarthrititis. The treatment must be given under close control of the patient. The dosage must be comparatively high to insure quick and adequate results. Large doses do not entail greater risk than small doses. The complications are often associated with rapid improvement in the articular symptoms. The grave complications consist of extensive and prolonged dermatitis, granulocytopenia and thrombopenic purpura; also encephalitis and bronchopneumonia. The author does not repeat the treatment in a patient who has had thrombopenic purpura. Arteriosclerotic patients with hypertension and with cardiac injuries and some patients with nephritis occasionally evince low tolerance to treatment with colloidal gold.

Chronic Polyarthrititis in Children and Gold Treatment.—Bille reports on 43 cases of the disease in children under 15 given treatment with colloidal gold; in 46 cases intramuscularly, in 16 intravenously, in 2 by mouth, with one injection a week and usually from six to ten injections in each course, under close control with examination of the blood and urine at least once between injections and daily control of the temperature. In all, sixty-four courses were given. The treatment was individualized, with initial dose usually of 5 to 40 mg. depending on the body weight, highest dose form 20 to 150 mg., the total amount in a course of ten injections from 100 to 1,000 mg. The treatment gave good results in 25 children; 11 were somewhat improved, and 7 unchanged. Complications, almost all mild, appeared in about half the courses of treatment and were independent of the amount of gold given. Encephalitis and purpura are the most dangerous complications in adults. None of the children had encephalitis; 1 case of purpura, with recovery, was the most serious complication in these cases. Albuminuria occurred more often than in adults.

*Congenital Hemolytic Disease: Prevention and Therapy. E. Lattes, p. 271.

Congenital Hemolytic Disease.—Prevention of the disease includes avoiding transfusion or intramuscular injections of Rh-positive blood into infant girls, girls and women all through their life of sexual activity when the blood of the infant, girl or woman is Rh negative. In case of isoimmunization of the mother, the sudden increase or lowering of blood antibodies after the eighth month of pregnancy is an indication for induction of delivery and replacement of the newborn infant's blood by transfusion immediately after birth. Transfusion of this type is also indicated immediately after birth in cases of acute jaundice in infants born at full term to isoimmunized mothers. Blood in the amount of 500 cc. is administered. Transfusion of Rh-negative blood is indicated in the great majority of cases of anemia from congenital hemolytic disease. The author reports good results with blood transfusion in 5 cases.

*Penicillin Therapy of Purulent Pleurisy and of Pulmonary Abscess in Infants. F. Toscano.—p. 323.

Penicillin Therapy of Purulent Pleurisy and of Pulmonary Abscess.—Combined intrapleural and intramuscular penicillin therapy is of value in purulent pleurisy of infants. Toscano reports favorable results in 7 cases. Pulmonary abscesses require continued introduction of penicillin into the abscess by means of aerosol inhalations. The solution of penicillin to be nebulized in oxygen should contain from 20,000 to 100,000 Oxford units of penicillin for each cubic centimeter of the solution. The patient should inhale from 5 to 8 liters of the oxygen-penicillin nebulization as the total dose.

*Preventive Vaccination Against Whooping Cough and Diphtheria in Infants and Young Children. G. Ramon, R. Debré, M. Lelong, R. Sohler and R. Richou.—p. 193.

*Modified and Latent Forms of Acute Meningitis and Abscess of Cerebrum in Patients Treated with Penicillin. L. Rouquès, M. David and Jean Pautrat.—p. 194.
Syndrome of Pantoast and Tobias. J. Chenebault.—p. 195.

Vaccination Against Whooping Cough and Diphtheria.—Ramon and his associates have resumed their investigations on immunization against diphtheria and whooping cough which were begun before the war. They had demonstrated on guinea pigs that when diphtheria toxoid was mixed with antipertussis vaccine its efficacy was increased from three to ten times. The authors continued their studies on experimental animals and on young infants with an antipertussis vaccine which is non-virulent and nontoxic and to which had been added diphtheria toxoid. The latter was concentrated, purified and freed from foreign elements, so as to avoid reactions to peptones and to other substances derived from the culture. Combining the vaccines not only makes it possible to reduce the quantity to be injected, but increases the chances of success. The authors think that it will be possible to immunize infants before they are 8 months old simultaneously against whooping cough and diphtheria. In the course of the second year of life the child, in accordance with French law, will be subjected to vaccination with a mixture of diphtheria and tetanus toxoids to which should be added avirulent whooping cough vaccine. This last formula will have the advantage of reinforcing the previously induced immunity to diphtheria and whooping cough and confer immunity to tetanus.

Modified Forms of Meningitis and Cerebral Abscess in Patients Treated with Penicillin.—Rouquès and his associates point out that acute meningitis and cerebral abscess of patients treated with penicillin often assume modified aspects and may even remain latent. It is not advisable to wait for the appearance of the classical functional signs before considering the existence of these complications. The authors present 2 cases. One concerned acute febrile meningitis manifested only by intense headache without muscular contracture or changes in the reflexes. The other case was one of a large cerebral abscess with osteomyelitis of the frontal bone; the

condition was so dormant that without the existence of papilledema one would have hesitated to affirm the existence of a pathologic process.

"Cure" of So-Called Acute Leukemia. R. Fauvert, J. Mallarmé and P. F. Petit.—p. 302.

*Brucellosis and Rapid Agglutination. J. Basset.—p. 303.

Cure of Acute Leukemia.—According to Fauvert and his co-workers acute leukemia or malignant leukosis is a subacute condition with a prolonged course, spontaneous remissions and occasionally even with a temporarily reversible blood picture. Four cases, in 2 adults and in 2 children, are reported, which presented an initial phase of characteristic and complete leukosis followed by clinical and hematologic remission. The duration of the remission was four years and one year respectively in the adults, and two and one-half months in the children. The treatment of these 4 patients consisted of rest exclusively. These facts must be considered in the evaluation of the efficacy of any therapeutic trial, and results should be acknowledged only after a follow-up of several months. Although satisfactory results had been obtained with penicillin, transfusions or perfusions of citrated blood, they should be considered only as symptomatic treatments. Exsanguination transfusion which was given to children did not prove more effective than simple transfusion or perfusion.

Rapid Agglutination in Brucellosis.—Basset believes that a positive reaction obtained with a rapid antigen may cause an erroneous serum diagnosis of brucellosis when certain unreliable commercial antigens are used. Only antigens should be considered of value which have been standardized and adjusted to the titer of a known serum. The more concentrated or the more rich in microbial bodies an antigen is, the less sensitive it is. For rapid agglutination an antigen of much higher concentration is required than for slow agglutination because of the considerable volume of serum used for rapid agglutination. Procedures are described by which such antigens may be obtained which then may offer considerable aid in the diagnosis of brucellosis at the sick bed.

Latent Spondylolithesis with Large Spondylolysis of L-5: Roentgenologic Discovery at Time of Acute Volvulus of Stomach. S. de Sèze, J. Durieu and A. Djian.—p. 120.

Reducible Discal Hernias and Sciatica.—Evidence is presented by de Sèze and Leverneux to the effect that certain posterior hernias of the intervertebral disk are reducible. This explains some discrepancies between the clinical aspects and the results of roentgenography. In certain cases, in which clinical signs of discal hernia exist, contrast roentgenography fails to disclose the typical notch. This is not surprising, because the roentgenologic examination is made with the patient in the recumbent posture, usually after rest, and in the posture which gives him the least pain. The discal notch might appear if such a patient were examined, with the aid of morphine, in the position in which the pain is most severe. The reducibility of some discal hernias explains also a certain number of negative surgical explorations in cases of sciatica which are then referred to as "nondiscal" or not due to herniation of a disk. The surgeon must be able to evaluate the consistency of the disk and must think of the possibility of reducible disk lesions and learn to recognize them. The reducible character of the discal hernia does not necessarily imply the benign character of the painful lumbosciatic syndrome. On the contrary, nothing is more annoying than are these "intermittent" hernias. After much loss of time, an operation may be decided on, but if the hernia is not detected and removed, the operation may be ineffective; if it is recognized exeresis may not suffice. These hernias, which are reducible by rest, pose the question of the advisability of a bone graft.

*Report on Treatment of Tuberculosis With Streptomycin. (Study of 225 Patients). E. Bernard and Miss Alice Lotte in collaboration with B. Kreis, J. S. Bourdin and G. Arnaud.—p. 165.

Streptomycin in Tuberculosis.—Bernard and Lotte treated with streptomycin 225 patients, 78 of whom had tuberculosis of the meninges, 54 miliary tuberculosis, 64 nonmiliary tuberculosis of the lungs, and the remainder tuberculosis of the larynx and pharynx. The average dose administered by intramuscular route was 1.5 Gm. (1,500,000 units) for twenty-four hours. Occasionally the daily dose was increased to 2 Gm., but some patients could tolerate only 1 Gm. or even less. At the initiation of the treatment all the patients were given additional three to eight intraspinal injections of 50,000 to 300,000 units, but in general 100,000 units of streptomycin every second day. The treatment by intramuscular route was continued for several months. There were recurrences in 14 of 22 patients in whom treatment was discontinued spontaneously after two to three months. In 5 patients there were recurrences in the course of the treatment after three to five months and in 1 patient even after seven months of treatment. Untoward reactions consisted of vomiting, vertigo and, in 1 case, erythroderma, but in the majority of the cases these reactions did not recur when the treatment was continued after a temporary discontinuance of three to four days. Vestibular disturbances were observed in 39 per cent of the patients. Thirty-one of the 78 patients with tuberculous meningitis were alive after six to eight months. In 22 of the 54 patients with miliary tuberculosis meningitis supervened before, during or after treatment. Thirty-six of the 54 patients, mostly those without meningitis, survived and presented a complete clearing up of their roentgenograms. Streptomycin proved to be a valuable preoperative or postoperative measure in cases of nonulcerating pulmonary tuberculosis. In laryngeal and pharyngeal tuberculosis the dysphagia subsided and the dysphonia and the lesions improved as result of the treatment with streptomycin. Improvement was obtained in isolated nonstenosing forms of bronchial tuberculosis.

Chemotherapy of Tuberculosis. E. Suter.—p. 324.

*Streptomycin in Treatment of Intestinal Tuberculosis. N. Markoff.—p. 329.

*P-Aminosalicylic Acid in Chemotherapy of Tuberculosis. L. Ragaz.—p. 332.

Streptomycin in Intestinal Tuberculosis.—Markoff presents a preliminary report on the supporting effect of streptomycin in the treatment of ulcerative intestinal tuberculosis. Streptomycin is administered parenterally, but also enterally in the form of high enemas with elevation of the pelvis and subsequent placing on the right side. In this way, the streptomycin can be carried to the ileocecal valve and beyond into the distal portions of the small intestine. The region of the ileocecal valve is the most frequent localization of the ulcerous and tumor-like forms of intestinal tuberculosis. The enema is given daily for two weeks. This enteral local treatment of intestinal tuberculosis with streptomycin has proved to be a valuable supportive treatment in the 5 cases in which it was employed. Only six months have elapsed since the authors tried this treatment. Their observations are similar to those in the United States. The intestinal symptoms were greatly improved. Roentgenoscopy suggests a healing of the ulcers, but complete repression of the tuberculous process has not been observed as yet. If the more distal portion of the colon and the rectum are involved, treatment by enema is likewise advisable. If tuberculosis involves the small intestine, particularly the proximal portions, oral therapy with streptomycin could be tried with the same doses as those used for bacillary dysentery.

P-Aminosalicylic Acid in Therapy of Tuberculosis.—Most of the patients treated had a progressive form of tuberculosis and a positive sputum. Internal treatment with divided doses of 10 to 15 Gm. per day, continued for a week and then followed by a week free of treatment, was the method most

commonly employed. This treatment was usually continued for several months. Improvement was observed in from 60 to 70 per cent of the patients with pulmonary tuberculosis. There was improvement in the general condition, increase in weight, decrease in temperature, improvement in the sedimentation rate and decrease in the number of bacilli in the sputum. A patient with renal tuberculosis was free from bacilli after two weeks and free from symptoms after eleven weeks. However, para-aminosalicylic acid did not pass the crucial test; it did not save 4 patients with miliary tuberculosis and 3 with meningitis. Favorable results were obtained in the local treatment of empyemas and abscesses by means of a 10 per cent solution of the drug.

*Bronchoscopic Study and Behavior of Bronchi in Course of Primary and Secondary Stages of Tuberculous Infection. (Concluded). A. Dufourt and P. Mounier-Kuhn.—p. 65.

Successive Cessation of Both Poles of Primary Tuberculous Complex. Nelly M. Schmid.—p. 100.

Bronchoscopic Study of Primary and Secondary Stages of Tuberculosis.—Dufourt and Mounier-Kuhn report 25 cases of primary infection, tuberculous bacillosis and epituberculosis in 22 female patients between the ages of 2½ and 20 years and in 3 boys between the ages of 12 months and 4 years, on 24 of whom bronchoscopy was carried out. This method of examination has been of considerable aid in elucidating the pulmonary manifestations which follow the primary infection. In uncomplicated primary infections the orifice of the lobar bronchus corresponding to the location of the primary focus appeared usually slightly congested, edematous and covered with a mucous secretion rich in polymorphonuclear leukocytes and macrophagocytes. It may contain bacilli. In cases of chronic epituberculosis edema of the main bronchus of the involved lobe may be the dominating feature, and the narrow central opening may be obstructed by a plug of tightly packed macrophagocytes. Compression of the bronchial wall by enlarged lymph nodes, in addition to the swelling of the mucosa and to the plug of the secreted material, may be responsible for bronchial occlusion. Rupture of a lymph node into a bronchus and formation of fistulas were observed more frequently than it has been presumed. Large fistulas are rare, but small fistulas, either single or multiple, occur frequently; they may be latent or manifested by occasional attacks of cough, pain in the chest or rise of temperature. As a rule the roentgenologic picture of the chest reveals only minimum changes limited to the inferior or median lung fields. The bronchial fistulas may heal completely or they may be responsible for various late clinical syndromes resulting from scar, cicatricial stenosis and bronchogenic dissemination.

*Recent Observations on Recrudescence of Diphtheria in Europe and on Efficacy of Ramon's Anatoxin. H. and M. Hinglais.—p. 899.

Recrudescence of Diphtheria in Europe.—According to the Hinglais, diphtheria has become the most common and the most fatal of the epidemic diseases in Europe after World War II. The average number of cases in the Netherlands during the period of 1933 to 1939 was 1,400, as compared to that of 38,000 during the period of 1941 to 1946. The corresponding numbers in Finland were 1,993 and 54,297, respectively; in the Iberian peninsula 1,119 and 27,474 respectively; in France 19,893 during the decade of 1928 to 1938 as compared to 45,541 in 1945; in Belgium 2,090 and 6,099 respectively; in Switzerland 2,264 and 4,981 respectively. In Hungary, where vaccination with Ramon's antitoxin was practiced on a large scale and organized methodically, a definite decrease in the number of cases was observed (from 14,500 in 1934 to 9,576 in 1946), and the same applies to Sweden and Denmark. In England mass

vaccination has been carried out since 1940-1941. The average number of cases during the period of 1935 to 1939 was 59,114, with 2,860 deaths (mortality rate 5.8 per cent) as compared with 18,596 in 1945 with 694 deaths and to 12,337 in 1946 with 472 deaths. These data and those published by the health service of New York City demonstrate the decisive part which vaccination played in the regression of the disease in England and in New York City. The rhythm of the drop in the mortality rate was the same as that of the drop in the morbidity rate, which proves that the vaccine is as effective with regard to mild forms as to grave forms of the disease. In spite of a certain failure margin which should not be denied, the methodic application of vaccination in a country may practically eliminate the disease in the course of several years.

*Armstrong's Disease (Lymphocytic Choriomeningitis). B. Kreis.—p. 1018.

Prolonged Icterus in Newborn Due to Incompatibility of Rh Factor. Part Played by Maternal Lactation. G. Desbuquois.—p. 1023.

Lymphocytic Choriomeningitis.—Kreis emphasizes that a filtrable virus which was discovered in the United States, may be the pathogene of certain forms of lymphocytic meningitis in which recovery occurs. History of contact with mice, a prodromal febrile period and a pronounced hyperleukocytosis in the cerebrospinal fluid aid in the diagnosis. The latter may be further confirmed by animal inoculation or by demonstration of certain reactions in the serum. The virus causes a lymphocytic infiltration of the choroid plexus when inoculated into the brain of mice. Experiments in man revealed that the disease may be reproduced experimentally by the subcutaneous, intramuscular or intravenous injection of 2 cc. of an emulsion of brain of mice containing the virus; after an incubation period of thirty-six hours to three days rise in temperature may occur at two or three intervals over a period up to three weeks, and the last febrile attack may be associated with late meningitic symptoms such as headache, vomiting and Kernig's sign. In contrast to the tendency of American authors to consider lymphocytic meningitis and choriomeningitis as synonyms, the virus is responsible for only a small number of these cases. The considerable number of persons examined at random who neutralize the virus suggests that Armstrong's disease is to be considered as one of the most important infections occasioned by an identified serum.

Hemorrhages after Hysterectomy (Fourteen Cases Observed During Two Years). R. Keller and L. Gioanni.—p. 83.

*Calcareous Arteritis and Its Treatment by Parathyroidectomy. A. Jung.—p. 87.

Parathyroidectomy in Calcareous Arteritis.—Jung reports 1 case of chronic hyperparathyroidism in a man aged 53. The patient had generalized arteritis with calcium deposits in the abdominal aorta, in the femoral and posterior tibial arteries, in the internal and external carotid arteries and in the choroid plexus. There was a calcified subacromio-deltoid bursitis and calcium deposits in the epiphysis. There was generalized osteoporosis, paradentosis and multiple dental caries. Abnormally large amounts of calcium were observed in the blood and in the urine. Two parathyroid glands were removed under local anesthesia. The calcemia was reduced from 12.2 mg. per cent to 11 mg. per cent and the calciuria from 40 mg. per cent to 13 mg. per cent. Pain in the back and in the shoulder disappeared and pain in the legs and feet was considerably relieved. Three years after the operation the patient was able to hike in the mountains and had resumed his work as an architect. Previous animal experiments had shown that injections of parathyroid extract in rats produced an increased calcium content of the heart and arteries which can be demonstrated both chemically and histologically. These results suggested the existence of chronic hyperparathyroidism with predominant vascular manifestations. The case reported is to be considered as the first clinical proof.

Book Notices

Pathology of Tumours. By R. A. Willis, D.Sc., M.D., F.R.C.P., Sir William H. Collins Professor of Human and Comparative Pathology, Royal College of Surgeons, London. Cloth. Price, \$20. Pp. 1044, with 500 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3; Butterworth & Co., Ltd., 4-5 Bell Yard, Temple Bar, London, W.C. 2, 1948.

The first part, 207 pages, deals with general pathologic aspects of tumors: definition, classification, "innocence and malignancy," experimental production, statistics, tumors in animals, mode of origin, structure and growth, direct spread, metastasis and hypothetical nature of neoplasia. The rest of the text, pages 208 to 992, covers systematically in 50 chapters the tumors in the different parts of the body. This is perhaps the most important, convenient source now available for thorough and reliable information about the pathologic aspects of individual tumors. There is a valuable list of select references at the end of each chapter, frequently with comments. In the case of main references and reviews, the authors' names are in capitals and the full titles are given. The 500 figures are all of personally studied structures, with emphasis on less familiar and special features. Needless repetition is avoided. There are many instructive reports of the author's own observations in Melbourne and London of more or less familiar aspects of tumors. The book is addressed primarily to pathologists, advanced students and investigators, but clinicians with special interest in cancer will find it of great interest and value. Willis states promptly and clearly his own present opinion in disputed matters in order "to avoid noncommittal vagueness," realizing fully that future advances may modify current views. Fourteen years ago Willis published his book on "The Spread of Tumours in the Human Body," also a notable book, and now is "Pathology of Tumours" is welcomed as an outstanding addition, soundly critical and comprehensive, to the literature on tumors.

Annual Review of Physiology. Volume X. Victor E. Hall, Editor, Jefferson M. Crismon and Arthur C. Glese, Associate Editors. Cloth. Price, \$6. Pp. 552. Annual Reviews, Inc., and American Physiological Society, Stanford, California, 1948.

The tenth "Annual Review of Physiology" is, like the previous volumes, replete with a wealth of information that has laboratory and clinical value. Practically all the reviews have been obtained from this country; only a few from abroad. Nevertheless, the contained information will interest everyone with research and progressive clinical interest. Included in the contents are discussions of physical properties of protoplasm, physiologic aspects of genetics, developmental physiology, physiology of reproduction, conduction and synaptic transmission in the nervous system, somatic functions of the central nervous system, vision, digestive system, blood cytology, heart, peripheral circulation, metabolic aspects of shock, respiration, anoxia in aviation, regulation of energy exchange, metabolic functions of the endocrine glands, heat and cold, physiology of sweating, pharmacology, the coagulation of blood, hemostasis, physiologic psychology and physiologic effects of radiant energy. This volume will need no introduction to those who are familiar with the earlier reviews. Others who have yet to make their acquaintance with it will find a collection of information that warrants the reputation gained by the book.

Aids to Diagnosis and Treatment of Diseases of Children. By F. M. B. Allen, M.D., F.R.C.P., Physician, Belfast Hospital for Sick Children, Belfast. Eighth edition. Fabrikoid. Price \$2. Pp. 268. Williams & Wilkins Company, Mt. Royal and Guilford Aves., Baltimore 2; Baillière, Tindall and Cox, 7 and 8 Henrietta St., Covent Garden, London, W. C. 2, 1947.

This book attempts to cover briefly the entire scope of pediatrics and to give aids to diagnosis and treatment. However, most of the material is inadequately covered, serious omissions are present and much of the material is obsolete. Intrathecal therapy is recommended for meningococcal meningitis, a procedure that has been discarded. None of the newer developments in the prophylaxis of rheumatic fever or the diagnosis and surgical treatment of congenital cardiac disease are mentioned.

There is little in the book that will be of aid to the student or practitioner.

Die Sauna: ihre Geschichte—die Grundlagen ihrer Wirkung—ihre Anwendung zur Prophylaxe und Therapie mit einem Anhang: Bau und Betrieb der Sauna. Von Dr. Med. Victor H. Ott, Privatdozent an der medizinischen Fakultät Zürich. Cloth. Price, 15 Swiss francs. Pp. 224, with 29 illustrations. Grune & Stratton, Inc., 381 4th Ave., New York 16; Benno Schwabe & Co., Klosterberg 27, Basel, 1948.

The author states that one of the most important tasks of physical medicine is to submit well established physical procedures to an impartial scientific investigation.

The Finnish "sauna bath" became popular in Europe after the Olympics in 1936. At that time the Finnish athletes considered the regular use of "the sauna" to be so essential to their physical fitness that they had a sauna bath built in Berlin.

The sauna bath is a sweat bath heated by a stone oven in a small enclosed room. Basically it is a dry hot air bath, but steam is produced occasionally by sprinkling a small amount of water on the hot stones. Flagellation with birch twigs is done to promote hyperemia of the skin. Cooling is performed by a brief plunge into cold water.

Dr. Ott has compiled his data on the effects of the sauna bath over a period of several years.

A good review of the history of sweat baths through the ages precedes the discussion of the author's own experiences. The report is based on questionnaires sent to 95 healthy persons who used the sauna spontaneously, and on observations of 130 patients at the Polyclinic for Physical Therapy at the University of Zürich with varying complaints, predominantly rheumatic diseases and "neurovegetative" disturbances.

The physiologic effects observed include increases in bodily temperature, pulse rate, blood pressure and respiratory rate, electrocardiographic changes and changes in the chemical and cellular composition of the blood. The author also reports therapeutic effects by means of representative cases, but obviously a much larger clinical study would be required to prove the reported clinical results.

A comprehensive discussion of experimental physical conditions such as temperature and humidity of the air at various locations in the sauna room, heat radiation and cooling after the bath is included.

An appendix gives detailed specifications for the building and maintenance of a sauna bath.

The author has presented a thorough review of the subject and his experimental observations seem sound; however, his conclusions concerning clinical results, which include indications and contraindications for the use of the sauna bath, appear to be premature on the basis of his small series of cases. There seems to be little likelihood that this ancient and rather crude procedure will be employed extensively in American medicine, but physicians interested in modern forms of thermotherapy may find this presentation interesting.

Fundamentals of Human Reproduction. By Edith L. Potter, M.D., Associate Professor of Pathology, Department of Obstetrics and Gynecology, School of Medicine, University of Chicago, Chicago. Cloth. Price, \$3.50. Pp. 231, with 92 illustrations by Alvin W. Meyer, F. A. A. B. McGraw-Hill Book Co., Inc., 330 W. 42nd St., New York 18, 1948.

This is an excellent reference or supplemental book for nurses on the subject of human reproduction. If used as a textbook it would require a skilled teacher, since there are none of the usual textbook appurtenances such as review questions, projects or other teaching helps. After the introduction, Part I proceeds in well planned sequence from a consideration of forms of animal life to the general pattern of reproduction, the factors responsible for body form and the number of offspring. Part II deals with the sex organs and their function, the development of the blastocyst and the formation of the placenta and a survey of embryonic and fetal development. In Part III, separate chapters are devoted to development of each of the following parts: brain and spinal cord, stomach and intestines, liver, pancreas, lungs, spleen, heart and blood vessels, kidneys and urinary bladder, organs of reproduction, glands of internal secretion, body framework, skin and accessory structures, and the face and sense organs. Part IV is devoted to birth and the future life of the infant.

There are excellent diagrammatic illustrations throughout the text. A notable feature is the series of photographs—twelve plates in number—which begins with the chorionic vesicle and

shows the embryo and fetus at various stages of development up to twenty-two weeks, including a roentgenogram of bony development at sixteen weeks. There are a good bibliography, a helpful list of visual aids and an adequate index. The book is well printed and attractively made. It can be recommended with enthusiasm for the use for which it was intended in nursing education or any other introductory course in embryology.

Introduction à l'étude de l'anesthésie: Chimie—biochimie—physiologie—physiopathologie—pharmacodynamie—thérapeutique—technique. Par J. Dautrebande, professeur à l'Université de Liège, E. Philippot, chef des travaux de thérapeutique expérimentale, et M. J. Dallemagne, assistant de chirurgie expérimentale. Préfets des cours de l'Ecole d'anesthésie de Liège. Paper. Price, 750 Belgian francs. Pp. 1235, with 288 illustrations. Masson & Co, 120 Boulevard St. Germain, Paris; J. Duculot, Gembloux, Belgium, 1941.

As the title implies, the book is an introduction to the study of anesthesia in all its aspects compiled with true continental thoroughness. It is dedicated, and is a worthy memorial, to Frank McMeekan that good friend of the senior author (Dautrebande) and of all anesthetists. During the past quarter century the publications of the senior author, a distinguished Belgian physiologist, have been useful to American anesthetists. The book is divided into three parts. The first (410 pages) deals with the fundamental concepts of physiology, biochemistry and pharmacology which influence, and are influenced by, depressant drugs and the anesthetic state. The second part (150 pages) is concerned with the chemical, physical and other properties of anesthetic agents which influence the absorption and elimination of them by the body. The third part (379 pages) deals with the clinical applications of parts I and II. It includes details of all the various techniques of administration, effects of various concentrations of the individual drugs, methods of determining concentrations and a general exposition of clinical anesthesia. Inhalational therapy, endotracheal techniques and other subjects allied to anesthesia are dealt with quite adequately. Part III is, in itself, a textbook on clinical anesthesia. As such, however, it is slightly handicapped by an obviously limited clinical knowledge and experience of the authors. A very complete bibliography (244 pages) of the English and French literature and an index follow the text. The excellent table of contents appears at the end of the volume instead of at the beginning. This monumental work deserves translation into English. Meantime it will prove extremely valuable to those anesthetists and students who read French. The Belgian editor, J. Duculot, and the Paris printers are to be congratulated on the arrangement, printing and binding accomplished under wartime conditions. A paper-bound book of 1,235 pages which opens flat in the reader's hands and stands hard usage without falling apart is a triumph of the publisher's art.

Mental Health in Modern Society. By Thomas A. C. Rennie, M.D., Associate Professor of Psychiatry, Cornell University Medical College, New York, and Luther E. Woodward, Ph.D., Field Consultant, Division of Rehabilitation, National Committee for Mental Hygiene, New York. Cloth. Price, \$4. Pp. 224. The Commonwealth Fund, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Square, London, E. C. 4, 1948.

This is a comprehensive and well written review of the social implications of modern dynamic psychiatry. The book deals particularly with developments in the field during and since the last World War. Included in its scope are factual and pertinent discussions of military psychiatry, the civilian readjustments required of the returned veteran, the role of the general practitioner in solving the problems of post-war rehabilitation and the contributions that can be made by social workers, psychologists, the clergy and by leaders in education and industry. Perhaps the only criticisms that can be made of this volume pertain to its implicit assumptions that much of the material it presents is of recent discovery, whereas in truth nearly all of the lessons we painfully "learned" during the last war were well known by 1920, were published in psychiatric journals and government reports, and were then tragically forgotten. Rennie and Woodward now remind us of the incalculable and protracted cost of war in human suffering and social turmoil, and we join with the authors in their fervent hope that this will be the last reminder we shall ever need. The book is highly recommended to physicians, social workers, clinical psychologists and all others interested in the field of social psychiatry.

Heart: A Physiologic and Clinical Study of Cardio-Vascular Diseases. By Aldo A. Luisada, M.D., Instructor in Physiology and Pharmacology, Tufts College Medical School, Boston. With a foreword by Herrman J. Blumgart, Physician-in-Chief, Beth Israel Hospital, Boston. Cloth. Price, \$10. Pp. 653, with 353 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, Maryland, 1948.

This text is written for the practitioner who desires to increase his knowledge of cardiovascular disease. It will be a valuable reference book also for medical students or post-graduate students reviewing this field. The field is covered competently; the book is well illustrated and has a very complete bibliography at the end of each chapter which includes not only the literature in English but also European references.

After a tabular history of cardiology and two chapters dealing with the development and function of the cardiovascular system, the author devotes two chapters to the clinical and technical (laboratory) study of the patient. The author has abandoned the usual etiologic presentation of the heart diseases and substituted an anatomical-clinical classification which he attempts to correlate with etiology. To the reviewer this seems only to lengthen the volume without achieving any clarification of diagnosis. The author complains in his preface that the etiologic classification of heart disease has resulted in mental laziness in formulating an exact diagnosis. Nowhere in his book does he stress that an adequate diagnosis of cardiovascular disease should include a statement of the etiologic factor, the anatomic lesion and the physiologic disturbance, as well as a functional and therapeutic classification. The latter two are becoming more important, especially in connection with patients who are recommended for rehabilitation and employment.

In general one can concur with the majority of his statements regarding diagnosis and therapy. A few topics on which some discussion would be expected are either omitted or only briefly mentioned. These are: the use of anticoagulants in coronary thrombosis with myocardial infarction; the low sodium diet in hypertension, and the use of penicillin in cardiovascular syphilis.

Bergey's Manual of Determinative Bacteriology. By Robert S. Breed, E. G. D. Murray and A. Parker Hitchens. Assisted by Sixty Contributors. Sixth edition. Cloth. Price, \$15. Pp. 1529. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

The new sixth edition of this standard reference, revised under the editorial chairmanship of Robert S. Breed, contains contributions from sixty well known specialists in the field of bacteriology. Changes in the presentation and relationships of almost every genus of bacteria have been made by specialists in consultation with the editorial board. Nearly three hundred new species are described. Because of increased knowledge the number of species described under fission fungi has increased from 1,335 in the fifth edition to 1,630 in the present manual.

The authors state that the present edition does not cover all the descriptions of species found in the literature for, as in all other branches of biology, many of the descriptions are so inadequate that the species described cannot now be identified. Additionally, many of the descriptions are obvious duplications of previous descriptions, while other so-called differences are based on nothing more substantial than the investigator's opinion. A completely new feature, the "Source and Habitat Index," has been added to this volume; the editors believe that it will be extremely useful both to teachers and investigators in determining the identity of a described species or whether a given species is new. Organisms cannot be classified before detailed study of their morphologic, cultural, physiologic and pathogenic characters is made, and the student is warned not to take too literally the descriptions which are drawn to represent average findings. Especially among bacteria, characters such as sugar fermentations, gelatin liquefaction, presence or absence of flagella or other identifying characters may vary.

New information for this volume has been taken from dark field motion pictures of motile cells and photographs taken with the recently developed electron microscope, revealing heretofore unsuspected facts regarding structural features. The book contains a wealth of references to both the domestic and foreign literature for the use of the student and investigator. The total number of pages of the book has been increased from 1,031 to 1,529. Additionally, each page contains approximately 20 per cent more material than the pages of the fifth edition. The structure of the contents of the book remains essentially the same.

Treatment by Diet. By Clifford J. Barborika, B.S., M.S., M.D., Assistant Professor of Medicine, Northwestern University Medical School, Chicago. Fifth edition. Fabrikoid. Price, \$10. Pp. 784, with 14 illustrations. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1948.

Much of the recent voluminous literature on nutrition has been revised and significant additions have been incorporated in the fifth edition. Tables summarizing the effects of vitamins on the body, sources of supply and recommended daily allowances give much information in a concise form. Other tables give analysis of foods that serve to meet basic requirements, symptoms of deficiency states, conditions that influence vitamin requirements and utilization and other significant data. In general, tables are well constructed, clear and contain sound current information. A number of excellent colored photographs add considerably to the value of the book. Seven photographs show comparative servings of foods in such a clear manner that they should be helpful to the physician in diet prescription. Effects of deficiency diseases are shown in three colored photographs and experimental studies in humans on a deficient vitamin C diet clearly show alterations in the healing pattern of wounds.

All the more common disease entities that have nutritional problems are briefly discussed. A number of suggested diets and supplementary instruction for patients form a valuable part of the book. The chapter on cutaneous disease and diet summarizes recent knowledge in the field. A large appendix containing many useful tables, weights and measures and recipes adds to the usefulness of the book. The extensive bibliography is helpful in finding original articles. A good table of contents and index make it easy to find subject matter, although it is disappointing that there is no index of the beautiful colored photographs. On the whole the book is well written, suitably illustrated and can be recommended to physicians interested in the dietary treatment of disease.

Pathological Histology. By Robertson F. Ogilvie, M.D., F.R.C.P., F.R.S.E., Lecturer in Pathology and Assistant in Forensic Medicine, University of Edinburgh, Edinburgh. Foreword by A. Murray Drennan, M.D., F.R.C.P., F.R.S.E., Professor of Pathology, University of Edinburgh. Third edition. Cloth. Price, \$10. Pp. 459, with 266 illustrations. Williams & Wilkins Co., Mt. Royal & Gullford Aves., Baltimore 2, Maryland, 1947.

In the recently published third edition of this book, much of the text is said to have been revised and expanded and fifteen new subjects and their illustrative plates added. The quality of the book, however, remains unchanged. Most of the illustrations are excellent examples of the pathologic processes which they illustrate. The color photography excels the photomicrographs in most medical textbooks made in this country, although oversteaining with eosin detracts from the beauty of many of the preparations. If this book were to be used as an atlas of pathologic histology and not as a textbook of pathology, it could be useful to American students in medical schools where classes are large, instructors are few and material limited in quantity or quality. Although this book is not intended to replace standard textbooks, its conciseness and attractiveness seem to offer the time-harried student a way out of his perennial dilemma. Unfortunately, however, textual material is inadequate for this purpose, and, aside from the gross and microscopic descriptions, the text is so limited in scope that it might be better to omit it and make the book entirely a laboratory atlas. This would increase its real usefulness to students and at the same time would decrease both the bulk and the cost of the book.

La chirurgie biliaire sous contrôle manométrique et radiologique per-opératoire. Par Pierre Mallet-Guy, professeur à la Faculté de médecine de Lyon, Lyon. René Jeanjean, Assistant à la Faculté, et Pierre Marion, Chef de Clinique à la Faculté. Paper. Price, 1200 francs. Pp. 138, with 170 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e, 1947.

This well documented discussion of cholangiography—the materials needed, the technic, the indications and the interpretations of manometric and radiologic procedures to be carried on concurrently with the surgical treatment of the biliary tract deserves careful study. The procedure is not new, having been given its great first impetus by Mirizzi, of Cordoba, Argentina, who in 1939 published a monograph on the subject. The text is based on 550 operative cases. The authors' technic has been somewhat simplified by the use of a portable, com-

pletely enclosed x-ray machine on wheels, sufficiently small to be wheeled under the operating table. The operating table itself is of unique pattern, supported at the two ends instead of by a central pedestal, thus permitting the placement of the x-ray apparatus under the operating table. A device is provided which permits quick simultaneous centering of the x-ray tube and the film holder in the midst of the operation. The authors consider carefully the problems of anesthesia incident to surgery in the presence of x-ray equipment. Numerous beautifully reproduced illustrations are accompanied by explanatory line drawings which make them perfectly clear to the reader. This book is worth while.

You Can Be Thin! Slenderness Through Psychology. By Herman Friedel, M.D. Foreword by Milton Jacovs, M.D. Fabrikoid. Price, \$2. Pp. 117. Caxton House, Inc., 9 Rockefeller Plaza, New York 20, 1948.

Another booklet about weight control with the usual diet lists, tables of caloric content of the common foods and, as an innovation in the popular literature of this field, with emphasis on the importance of psychological factors—such as inner conflicts and frustration—in the development of obesity. This will hardly suffice to increase the number of persons who can reduce their weight to or below normal through their own efforts, as promised in the title of this booklet. But it may be useful education for the obese subject if it helps him to understand why his physician tries to explore his personal problems as part of his examination and treatment.

Motivation in Health Education: The 1947 Health Education Conference of the New York Academy of Medicine. Cloth. Price \$1. Pp. 53. Columbia University Press, 2960 Broadway, New York 27, 1948.

Four qualified contributors present a well rounded clinical analysis of the basic problems of health education and how these may eventually be resolved. Every health educator will encounter in each of the contributions numerous examples of problems with which he or she has wrestled, often despairingly. These matter of fact introspections are both refreshing and encouraging. They demonstrate that health education is not the intangible, formless problem that many are apt to consider it but a living, pulsing subject closely interwoven with all human activities. Physicians as well as lay workers in health education will obtain helpful orientation through consultation of this volume.

Confrontations radio-anatomo-cliniques. II. Publiées sous la direction de M. Chiray, R. A. Gutmann, et J. Sénéque. Paper. Price, 465 francs. Pp. 69, with illustrations. Gaston Dolin & Cie, 8 place de l'Odéon, Paris 6^e. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e, 1947.

A previous review in these pages concerned volume I of this series of 42 case reports. The reviewer is favorably impressed with the choice of the cases and the complete analysis of the roentgenologic, anatomic and clinical aspects. Differential diagnosis is thoroughly considered. Many of the cases are gastroenterologic, but a number of documents relate to osseous pathology. The photographs of the anatomic specimens add to the value of the presentations. This series of "dry clinics" is presented on a high plane of scientific excellence.

Healing Herbs of the Upper Rio Grande. By L. S. M. Curtin. Boards. Price, \$7.50. Pp. 281, with 80 drawings by P. G. Napolitano. Laboratory of Anthropology, Santa Fe, N. M.; San Vicente Foundation, Inc., 984 Acequia Madre, Santa Fe, N. M., 1947.

This book contains a series of brief discussions on articles ranging from Mexican oil (aceite mexicano) to love-vine (yerba mala) arranged alphabetically according to the Spanish name. If the book is not accepted as a therapeutic guide it offers some rather unusual bits of information presented in a somewhat popular style. This is essentially a collection of statements on primitive herbal medicine.

Some Fundamental Principles of Metabolism. By L. H. Newburgh, M. W. Johnston, and J. D. Newburgh. Third edition. Paper. Price, \$2. Pp. 70, with 20 illustrations. J. W. Edwards, Ann Arbor, Michigan, 1948.

This monograph offers to physicians some basic knowledge of the manner in which the body uses food and water. The physics and chemistry concerned are beyond the depth of most practicing physicians; yet a basic knowledge is essential, particularly in controlling such conditions as obesity, undernutrition, edema and fever.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

METHYL ALCOHOL INTOXICATION

To the Editor:—Recently I was asked to testify on the effect of methyl alcohol on a man. Please furnish the additional needed information. The patient was an apparently healthy man about 45 to 50 years old. He had had several teeth extracted shortly before being arrested for drunkenness and had taken acetylsalicylic acid ("aspirin") tablets for pain. He had taken whisky during the previous evening and the morning of his arrest. About noon that day he drove his car about 60 miles. His car contained "zerone" antifreeze. "Zerone" contains 90 per cent methanol (methyl alcohol). The odor of the antifreeze was strong in the car, especially when all the windows were closed and the heater (hot water type) was turned on. When he was arrested, at about 3 p. m., the arresting officers stated that he was so drunk that he could not stand up, his speech was slurred and he had to be assisted to the jail. About one hour later he was released from jail, and at that time was able to write his name when he posted his bond. He recognized the difference between a one dollar bill and a five, and could walk straight without assistance. Have cases of intoxication occurred from inhaling methyl alcohol antifreeze? Would the fact that he had taken some whisky make the effect of the fumes greater? Would the effects of the whisky, antifreeze, and acetylsalicylic acid have caused him to be more stuporous than whisky alone? Does the presence of whisky (ethyl alcohol) in the body slow down combustion of methyl alcohol? V. Fallenberg (Soliman, *Manual of Pharmacology*, 1936, p. 682) stated "... if methyl is mixed with ethyl alcohol, as in liquors, the combustion is incomplete, and harm results from relatively small doses." Would a man as drunk as the arresting officers said that he was have been able to recover from whisky intoxication as quickly as he apparently did?

Joseph W. Chinn, M.D., Tappahannock, Va.

ANSWER:—The extraction of the teeth may have interfered with his driving, particularly since he may have been given procaine hydrochloride with epinephrine. The acetylsalicylic acid would not have effect on his condition unless it had been taken with codeine, and even then the chances are that the effect would have been negligible. The alcohol which he imbibed the night before was probably eliminated before noon the next day. However, the alcohol that he took the next morning would most likely have been present in his blood at noon and possibly for several hours thereafter.

The inhaling of alcohol fumes definitely increases the amount of alcohol in the blood. An instance is known of considerable discomfort and disorientation caused by sitting in a car filled with alcohol fumes. A specimen of urine taken about an hour afterward revealed 0.025 per cent alcohol, which is about the amount that one would have had from an ordinary "shot." Intoxication from the inhaling of methyl alcohol is a definite possibility.

It is likely that the subject was under the influence of ethyl alcohol before he inhaled the methyl alcohol fumes. It is fairly well established that methyl alcohol is less poisonous than ethyl alcohol if the methyl alcohol can be prevented from being oxidized to formic acid. Røe explained that ethyl alcohol in the stomach prevents absorption of ingested methyl alcohol. Also, formic acid ordinarily produced by the oxidation of methyl alcohol will not be formed when ethyl alcohol displaces methyl alcohol in the respiratory organs. In the medicolegal case under discussion, it seems that the subject had consumed the antidote before he was exposed to methyl alcohol. There is, therefore, little likelihood that the methyl alcohol inhaled was an important factor in his state of intoxication. The acetylsalicylic acid would have had no effect on his condition unless toxic doses had been taken, and evidence is lacking that such was the case. The apparent quick recovery is not typical of methyl alcohol poisoning, but commonly occurs when a person is sufficiently stimulated by his surroundings to become temporarily sober.

TINEA CAPITIS

To the Editor:—Two small boys, ages 7 and 9, have tinea capitis. They have been under the care of a dermatologist for four months. The Wood light shows that the infection is still active. The mothers are intelligent and cooperative, the hair is kept closely clipped and thoroughly scrubbed every night and the salve applied as directed by the dermatologist. What further treatment can be given to hasten cure of their infection?

Eva Cutright, M.D., Wooster, Ohio.

ANSWER:—Tinea of the scalp may be treated by either roentgenologic epilation, manual removal of infected hairs, topical applications or combinations of the three methods. None of these provides a rapid cure, and the choice of method employed depends in large part on the circumstances in each case. It is desirable first to identify the organism from culture, for tinea capitis due to *Microsporum lanosum* usually responds readily to treatment by manual removal of infected hairs and topical applications, whereas that due to *Microsporum audouinii* is rather resistant to such therapy. Topical therapy alone is usually adequate when there is pustular involvement of the scalp.

If in the aforementioned instances there are no other children at home who might become infected and if the youngsters can be trusted to protect their playmates and schoolmates by wearing caps constantly and not exchanging them, it would be well to continue with conservative treatment, which is the application once or twice daily of an ointment of 5 per cent salicylanilide in "carbowax 1500" over the entire scalp followed every few days by a thorough washing of the scalp with tincture of green soap. After the shampoo, when the scalp is free of ointment, it should be examined under the Wood light and all infected hairs removed with a tweezer. These hairs can be detected easily, for they assume a bright green color under the Wood light. If there is not sufficient improvement after a few weeks with this treatment, epilation may then be accomplished by means of roentgen therapy. The technic is exact and must be executed with skill and caution. In one sitting an epilating dose of roentgen rays is administered to the entire scalp with the five point method of Kienbock-Adamson. In three weeks the hairs and with them the fungi begin to fall and, with the use of strips of adhesive tape, those hairs which still adhere are removed. The scalp then should be examined under the Wood light to detect the presence of any scattered infected hair stubs, which should be extracted so that the scalp is entirely bald. An antiseptic ointment, such as salicylanilide, ammoniated mercury or sulfur, should be applied daily during this period until there is a regrowth of hairs. New hairs begin to grow in again after one to three months. The new hair is usually vigorous. On rare occasions the new hairs may differ in quality from the old—they may be straighter or more curly, finer or coarser in texture, and they may even change a little in color. The new hairs should be examined with the Wood light at intervals for several months.

In experienced hands, the treatment of tinea of the scalp by roentgen epilation has proved safe and reliable in thousands of instances. But it must be emphasized again that the treatment is an exact one to be administered with caution. It should be used only by one skilled in the use of roentgen rays for epilation of the scalp if permanent ill effects are to be avoided.

COLD ALLERGY

To the Editor:—Several of my patients suffer from respiratory allergic attacks precipitated by contact with cold air. Is it possible to desensitize these people to cold?

M.D., Connecticut.

ANSWER:—While attacks of asthma are frequently precipitated or aggravated by exposure to cold, patients in whom this is the primary immunologic cause of such attacks are unusual. Such patients usually have other manifestations in addition to nasal and bronchial symptoms on exposure to cold. Urticaria and angioneurotic edema are not only the most frequent associated manifestations but generally the main or only manifestations of cold allergy. In addition, various degrees of prostration associated with a sudden fall in blood pressure may occur when the exposure is sudden and the surface area chilled is extensive.

The cases mentioned by the inquirer are probably not primary cold allergy. Patients who are sensitive to inhalants and have symptoms of either nasal allergy alone or bronchial and nasal allergy are not uncommonly intolerant of cold. This is generally due to the irritating effect of cold air on a labile and irritated mucous membrane which responds rapidly to all types of nonspecific irritants (smoke, odors, inorganic dust) with increased edema and therefore increased nasal or bronchial obstruction. Treatment of asthma precipitated by cold depends

on the determination of whether the symptoms of asthma are due to primary cold allergy or to the more common effects of nonspecific irritation (Urbach, E., and Gottlieb, P. M.: *Allergy*, New York, Greene and Statton, 1946, pp. 411-415; Cooke, R. A.: *Allergy in Theory and Practice*: Philadelphia, W. B. Saunders Company, 1947, pp. 482-485).

Primary cold allergy is extremely difficult to treat. The simplest treatment, suggested by Horton and Roth of the Mayo Clinic, is the immersion of the hands or arms in cool water for one or two minutes twice daily. The temperature of the water is gradually lowered from 65 degrees F. until the patient is able to tolerate water at a temperature of 45 degrees F. Ice rubs or cool showers have been suggested by some allergists. Other methods depend on increasing the patient's tolerance of histamine by daily injections of small doses of the drug, gradually increasing the interval of injections to once a week. Antihistaminic drugs have recently been suggested in doses of 50 to 100 mg. every four hours as needed. These and numerous other measures reviewed in the textbooks mentioned are rather lame suggestions for therapy of a most difficult condition. The results are seldom good in cases of asthma due to primary cold allergy.

As for the more commonly encountered condition of intolerance to cold on a nonspecific basis in patients sensitive to inhalants or occasionally to foods, the treatment depends primarily on the cause of the respiratory allergy. Inhalants to which the patient is clinically sensitive should be removed from the patient's environment if possible. If this cannot be accomplished satisfactorily (as in sensitivity to pollen, mold and house dust), treatment by increasing the tolerance through injections of the antigens is necessary. Foods to which the patient is sensitive should be eliminated from the diet. The more successful treatment of the primary allergy the less will nonspecific irritants affect the respiratory mucosa. Meanwhile the patient should be protected by adequate clothing during cold weather. Commonly such patients protect the mouth and nose by the use of a scarf to avoid breathing cold air.

NUTRITION IN ILLNESS

To the Editor:—I am involved in a discussion on the type of nutrition most appropriate during acute illness, particularly febrile illness. Both sides agree that protein is necessary but disagree on type. One side maintains that as much meat and eggs should be given as the patient can tolerate without inconvenience, as those proteins are most complete for rebuilding of tissues, and that vitamins should be given in abundance. The other side maintains that protein should be given only as milk and vegetables to prevent overstimulation of metabolism by excess protein and also to avoid the toxic effects of nuclear proteins and nucleic acids. It also asserts that vitamins should be given sparingly to prevent invading micro-organisms from receiving the benefit of growth stimulation. What are the exact reasons for restriction of meat in certain diseases, such as nephritis? M.D., Canada.

ANSWER:—The acute period of a febrile illness such as pneumonia is usually of such short duration that the nutrition problem is chiefly one of nutrient fluids which may be taken with a minimum of effort on the part of the patient and with emphasis on the liquid rather than on the protein. Milk and orange or other fruit juices have been judged most suitable at this stage. As soon as the acute stage of fever is past, generous amounts of protein should be fed to check its rapid loss and to prevent hypoproteinemia. A variety of tender meats, eggs and milk supplemented by cereal and vegetable proteins should be used. At least 1 Gm. of protein per kilogram of body weight should be given, this being increased up to 1.5 or 2 Gm. per kilogram if serum proteins are already low, until normal serum protein levels are reached. The added growth requirements of children may bring the levels needed for them up to 4 or 5 Gm. per kilogram of body weight as shown by Harrell for children with Rocky Mountain spotted fever. The relation of protein to antibody formation reported by Cannon suggests a further reason for maintaining adequate protein levels as a protection against infection.

Vitamins should not be restricted in infections. Any condition such as fever which increases metabolism increases the requirement for thiamine. In tuberculosis generous intake of ascorbic acid is necessary to maintain normal plasma levels and appears to reduce the extension of infection to the digestive tract. The incidence of deficiencies of nicotinic acid and riboflavin in patients was also found higher than average. The observation that vitamin A tends to disappear from the blood during fever and the favorable results with the use of vitamin A in animals with tuberculosis indicate that it should not be restricted in infection.

The exact reasons for restriction of meat in nephritis are not obvious. Possibly the more severe effects of large quantities

of meat protein on rat kidneys compared with the simple hypertrophy found with equal levels of casein have influenced some. In other cases, no doubt, such restriction is used as a simple way of reducing protein intake. Meat also is acid forming, and the use of basic diets in nephritis has received some favorable reports. Protein consumption should not be reduced below the minimum metabolism. This with adequate intake of energy may approximate 0.5 Gm. per kilogram of normal weight. Lower intakes would not spare the kidney and would deplete body protein. In the nephrotic syndrome the protein intake should equal the minimum metabolism plus the albumin excreted plus enough to build the depleted serum protein up to normal.

ARTERIOSCLEROSIS AND DIABETES

To the Editor:—A physician 88 years of age, a recognized early authority in roentgenology, has been diabetic for years and is now suffering from the vascular changes that may take place in the advanced years: arteriosclerosis, hypertension, vascular spasm—but no visible retinal hemorrhages. He has macular degeneration of the left eye and has had an embolus that first involved the central retinal artery of the right eye and blocked lower retinal arteries, thus resulting in a blind upper field but with preservation of reading vision in this eye. Other vascular involvements of the lower extremities have occurred but his brain has remained clear. He has circulatory impairment which involves the right lower extremity when suddenly assuming sitting or erect position. While lying down he is able to move the lower extremity at will, but when erect the right leg is somewhat paretic, at times causing him to fall. Most of the time while erect he favors it by support and by chair to chair progress. He has become interested in the possibilities of ether as a therapeutic agent in the terminal stages of arteriosclerosis. I have been able to obtain only short, incomplete references to the use of ether. What are the references stating amount or frequency of dosage and possibility of its use intramuscularly?

Alfred Dean, M.D., Grand Rapids, Mich.

ANSWER:—The condition described by the correspondent is naturally an irreversible process of advanced cardiovascular disease which fortunately has left the mental capacities intact. There are obviously multiple arterial occlusions in various segments of the vascular tree. The lesion in the right lower extremity sounds like a neurologic one. If the reflexes are hyperactive, an upper motor neuron lesion is apt to be present, possibly on a cerebrovascular basis; vascular lesions of the cord are known to occur. Finally, the patient may have a diabetic neuropathic condition in the peripheral nerves producing an areflexia at the knee or ankle. Certainly a neurologic examination is in order, for the paresis may be even independent of the generalized vascular sclerosis.

The advocate of intravenous ether therapy for diabetic gangrene, Dr. R. A. Katz, has abandoned the intramuscular use of ether because of the tissue reaction caused by the injection of ether into muscle. He later advocated the intravenous use of a 2.5 per cent solution of ether, 2 liters daily for twelve days, followed by a rest of two days after which twelve more daily treatments are given.

In a situation as described by the inquiry, the urge for active therapy should be tempered by the recognition of harm which may result from such treatment in a patient aged 88 years with a nerve lesion which is only indirectly vascular, perhaps purely diabetic.

CHILDREN'S SHOES

To the Editor:—"Experts" in children's shoe departments have expressed widely divergent opinions on the type of shoe that should be worn by my children. Parents ask advice on the subject, and I have been unable to find a satisfactory answer. Assuming abnormality is absent and the proper size is worn, does it make any difference whether a child wears sandals, slippers, shoes with ankle support, soft or hard sole shoes, shoes with or without arch support, or shoes with or without an elevated heel? From the orthopedist's point of view, is there any contraindication for the normal child to go barefooted most of the time?

M.D., Florida.

ANSWER:—The fourth line of the query contains an important assumption that might be debatable.

A child walks on the same surfaces as its mother and father; viz., hard floors, cement sidewalks and asphalt streets. It should have, therefore, the same degree of support and protection.

In the case of normal feet and a proper fit of shoes, it makes little difference whether the child wears sandals, slippers, shoes without ankle support, hard soles, shoes without arch supports or shoes without "elevated" heels (inquirer means "tilted" rather than "elevated" heels), providing occasional observation does not reveal ankle valgus or pronation.

Regarding the question of "going barefooted most of the time," the answer depends on the ground. The only places a child should go barefooted are in warm sand on a beach and in the bath tub.

SUBJECTIVE HEAT SENSATION

To the Editor:—A 35 year old Mexican male patient is robust, stout, apparently healthy and weighs 190 pounds (86.2 Kg.). He was in the Army for about four years, and served in Italy. On his discharge in 1945 all tests and examinations were negative in result. Two months ago he began experiencing a sensation of heat, or hot flash, which starts on the medial surface of the right foot about the plantar area and extends to the ankle. At times, it seems to involve the lateral surface of the right thigh. After the hot flash is over he says that it seems that the area involved contracts. This same sensation involves the nuchal area and the right side of the face, causing a similar feeling of contraction. Yet when he touches the areas involved they do not feel hot. His symptoms actually began in 1937, when for three days he had a hot sensation posteriorly beneath the lower rib margin. This feeling then extended to the neck, head and face with a tremor of the right lower eyelid. This was soon followed by generalized headache with nausea. On the third day of the attack, about 10 a. m. he lost consciousness, his head turned to the right, his face became cyanotic, and he salivated profusely. In about five minutes he "came to" and was taken to the emergency hospital, where he was released after a short period of rest. Diagnosis was not made and treatment was not given. He has consulted many physicians but has been unable to obtain relief from the feeling of heat in his foot, neck and right side of face. He has been told by various doctors that there is nothing the matter with him. The symptoms are aggravated when he gets angry or excited. Physical examination was essentially negative in result. The blood pressure was 130 systolic and 84 diastolic. Deep reflexes were hyperactive. Serologic reactions for syphilis are negative. He is nervous most of the time, stating that he is worried about having an attack, as in 1937. What suggestions do you have regarding diagnosis and treatment? He had the symptoms while in the Army but was told that he was shamming. M.D., Texas.

ANSWER.—In the absence of all objective evidence of involvement of the nervous system, the subjective complaints must be analyzed to decide whether it is likely that they reflect the presence of a disturbance in that system. One may encounter in nervous disorders, disturbances of long duration which, even though they disturb structure, may give no objective evidence that they exist. The subjective complaints must be analyzed with the following points in view: 1. Do they have a consistent anatomic distribution? 2. Do they have a consistent behavior, compatible with a disturbance of nerve function? In regard to the distribution, it is seen that the symptoms are always found on the right side of the body, involving the right foot and ankle, thigh, and the nuchal area and the right side of the face. This would correspond, if the condition is neurologic, to a disorder in the left hemisphere. However, there is no consistency as to the areas involved; it may be the foot or the thigh, or the neck or the face. It is also pointed out that there is no progression of the symptoms over the body which would indicate "a cortical spread." If the subjective complaints were to start in the foot, they should then travel to the leg, the thigh, the trunk, then the arm and the face, and, if he is a right-handed man, some disturbance of language should be present.

The character of the symptom, which is a feeling of heat, could be of neurologic origin, but the fact that it is continuously present, especially in the foot, is a strong indication that it is not. Taken as a whole, the lack of consistency of the distribution of subjective complaints and the fact that the behavior of the complaints does not conform to that usually seen in organic disease of the nervous system would lead one to suppose that such does not exist. The nature of the disorder is not clear; the fact that it reproduces itself in somewhat identical fashion would lead one to believe that it is not an emotionally determined symptom; the possibility might be considered of a neurovascular disorder or even one of the disorders associated with histamine. While toxic phenomena are usually bilateral in character, it could be pointed out that histamine cephalalgia will usually occur only on one side of the face and repeat itself in identical fashion. It might be wise to give this patient a trial with antihistamine and/or ascorbic acid. One might determine whether histamine would precipitate or increase the subjective complaints.

IRRADIATED BLOOD

To the Editor:—What is the status of ultraviolet irradiation of the blood, and the "Knott hemo-irradiator"? Is it regarded as of clinical value?

Thomas P. Butcher, M.D., Emporia, Kan.

ANSWER.—There is no conclusive evidence that irradiation of the blood with ultraviolet light has merit. The studies in this field have suffered from the lack of adequate controls. The greatest possible usefulness of ultraviolet light in relation to blood lies in the radiation of pooled plasma to inactivate the virus of homologous serum hepatitis. However, the proper technique for such disinfection of plasma has not as yet been perfected.

EARLY ACQUIRED SYPHILIS

To the Editor:—A girl with active syphilitic lesions gave as her only source of contact a boy who had no history of either primary or secondary lesions and whose physical examination was normal. His qualitative Kahn reaction was positive. A quantitative test was not done at that time. He was treated with the twenty-six week Army plan of treatment consisting of forty injections of oxaphenarsine hydrochloride and sixteen injections of bismuth compound. His blood Kahn reaction was still positive after treatment with eight quantitative units. Spinal fluid was normal. Three months later the blood Kahn reaction was doubtful. No therapy had been given. Please discuss further therapy of this case assuming that the blood Kahn reaction remains positive.

M.D., Kentucky.

ANSWER.—It seems likely that the boy had early acquired syphilis. The twenty-six week army plan of treatment is usually effective. The serologic response of the boy seems to be that of early syphilis adequately treated. At the end of treatment, the titer was 8 and three months later, it had dropped to doubtful. Ordinarily this indicates a satisfactory response, and a negative reaction should be expected within a few months. As some patients' serologic reactions decline in titer slowly, a period of eighteen months from the beginning of treatment should be permitted to elapse before further treatment is considered.

If at the end of eighteen months following the institution of treatment the reaction is still positive and no lesions are present, the boy may be considered to have seroresistant syphilis, or if the titer has risen, a serologic relapse, or a reinfection. In either event, the boy should be given the benefit of an adequate course of penicillin, for which there are many treatment schedules. A simple schedule is that of 600,000 units daily of penicillin-oil-wax for ten consecutive days. Subsequent to this, if the spinal fluid is again negative and the physical examination reveals no evidence of syphilis, no further treatment is indicated.

MALARIA

To the Editor:—Living in an area where malaria is epidemic, I am particularly interested in an editorial in The Journal (p. 1176, August 2, 1947) in which the idea was suggested that "plasmochin" is advocated for use in conjunction with pentamidine in the treatment of malaria due to *Plasmodium vivax* to eradicate extra erythrocytic forms. Is this now admitted as routine therapy? I understood that it was applicable only for malignant forms.

M.D., China.

ANSWER.—There is a misconception of the article which appeared in editorials and comments of THE JOURNAL wherein it was assumed that "plasmochin" was advocated in conjunction with pentamidine in the treatment of *vivax* malaria. The improved treatment of malaria with pentamidine includes its simultaneous use with quinine but not "plasmochin." Actually, pentamidine is a less toxic and more effective compound than "plasmochin" and replaces the latter in the treatment of malaria. The dosage used in studies to date is 2 Gm. of quinine and 30 mg. of pentamidine in three doses daily for two weeks. Although this therapy has not been used extensively in the field, it has been found that recurring cases among former servicemen have disappeared completely after this type of ambulatory treatment.

HYPOGONADISM

To the Editor:—Please outline the treatment of hypogonadism in a girl aged 22 who has no mammary development, no pubic hair, primary amenorrhea, no development of vagina and the frame of an immature girl.

Louis A. D'Alecy, M.D., Staten Island, N. Y.

ANSWER.—There is insufficient information to permit determination of whether this girl is suffering from primary pituitary insufficiency or from congenitally aplastic ovaries with sexual infantilism. The distinction is important, since treatment for the latter condition is so much more satisfactory. There are many physical signs which will help in the differential diagnosis, and there is one helpful laboratory procedure: assay of the urine for gonadotropins, which assay gives a high reading in the presence of aplastic ovaries and shows little or no gonadotropins in cases of pituitary insufficiency. Some encouraging results have been obtained with the use of estrogens in the treatment of girls suffering from congenitally aplastic ovaries. A recent review of this subject can be found in the October 1947 issue of the *Journal of Clinical Endocrinology* (Lisser, H.; Curtis, L. E.; Escamilla, R. F., and Goldberg, Minnie B.: The Syndrome of Congenitally Aplastic Ovaries with Sexual Infantilism, High Urinary Gonadotropins, Short Stature and Other Congenital Abnormalities. Tabular Presentation of Twenty-Five Previously Unpublished Cases, page 665).

HYPERTHYROIDISM AND PREGNANCY

To the Editor:—Please inform me regarding management of pregnancy with hyperthyroidism being adequately controlled with propylthiouracil. The patient is a young woman who had two previous pregnancies with a moderate nausea and vomiting in the first trimester. Thyroid enlargement and symptoms of toxicity developed about two years ago and reached a severe stage with extreme nervousness, weakness, weight loss, and tachycardia. Her basal metabolic rate was between plus 60 and plus 70. For the past five months symptoms have been absent and she has gained weight and strength. Tachycardia has disappeared, and her basal rate has dropped to the upper limits of normal. She receives 150 mg. of propylthiouracil daily. Two months ago she became pregnant; she is beginning to have anxiety symptoms, although there has been as yet no return to a toxic state.

Burrell F. Eckardt, M.D., Sheboygan, Wis.

ANSWER:—The literature dealing with hyperthyroidism in pregnancy was recently reviewed by R. O. Mussey, S. F. Haines and E. Ward (*Am. J. Obst. & Gynec.* 55:609-618 [April] 1948). Thiouracil and related drugs have been used to control hyperthyroidism in pregnant women in a small number of cases reported in the literature. The occurrence of hyperplastic thyroids in a few of the fetuses calls for caution in the use of these drugs in pregnancy, although in a few cases they have been successfully used without demonstrable harmful effects. Of the goitrogenic drugs so far employed in the treatment of hyperthyroidism in pregnancy, reports seem to indicate that propylthiouracil can be used with greatest safety to the mother.

In 30 instances in which the patients received treatment at the Mayo Clinic, hyperthyroidism complicated pregnancy. The treatment carried out by Mussey, Haines and Ward included oral administration of Lugol's solution (strong iodine solution U. S. P.) and thyroidectomy for hyperfunctioning adenomatous goiters and Lugol's solution plus thyroidectomy, if needed, for exophthalmic goiter. Pregnancy did not seem to influence the course of hyperthyroidism in most cases. Likewise, proper treatment of the hyperthyroidism allowed the pregnancy to proceed normally. The standard treatment of hyperthyroidism by iodine and thyroidectomy can be carried out safely in the great majority of cases of hyperthyroidism complicating pregnancy and should be employed in this case if toxic symptoms appear.

HISTAMINE IN GASTRIC ANALYSIS

To the Editor:—References which I have for using histamine in gastric analyses say to use 0.1 mg. histamine for each 10 Kg. of body weight. Another reference advises 0.5 mg. as a total for the test in 1 cc. of solution. Does this quantity refer to histamine acid phosphate, or to histamine itself? If to the latter, may histamine acid phosphate be used in a gastric analysis? I have a solution of histamine acid phosphate, 0.55 mg. in 1 cc. (equivalent to histamine 0.2 mg.). In order to give 0.5 mg. histamine as my reference states, should I give 1 cc. of my present solution or give 2.5 cc. of the solution? In a recent patient whose blood picture was that of pernicious anemia I found no free hydrochloric acid after alcohol or histamine. The amount of histamine used was 0.55 mg. histamine acid phosphate. The patient weighed 150 pounds (68 Kg.). Is this a satisfactory test?

M.D., Kentucky.

ANSWER:—On looking over the statements regarding this subject in standard reference books, one is amazed at the differences in dosages suggested. Some of this confusion apparently arises because of the number of preparations of histamine which are commercially available. The drug may be purchased as acid phosphate or the dihydrochloride. The active portion of these substances is the histamine which they contain. The amount of histamine base in acid phosphate represents 36 per cent and in the dihydrochloride 60 per cent. The dosage used should always be calculated in terms of the histamine base. Either salt may be used, and both of the compounds should be dissolved in isotonic sodium chloride solution.

The usual dose of 0.1 mg. of histamine base for each 10 kilograms of body weight may perhaps be a little high. No harm will be done, however, if no more than 0.7 mg. is used. Satisfactory results can be obtained by using 0.3 to 0.5 mg. of histamine base.

ACNE VULGARIS

To the Editor:—I am seeking information on the treatment of acne vulgaris with estrogenic substances, particularly in male patients. What are specific dosages, therapeutic regimen and limitations of this therapy?

Lieut. Donald H. Ewalt, M.C., Fort Sill, Okla.

ANSWER:—Estrogenic substances should not be used in the treatment of acne in either boys or girls. They may have a profound effect on the patient, which would not be desirable. There is no assurance that they would have a good effect on the acne itself. It is suggested that other methods be employed for acne rather than hormone therapy.

ANAL FISTULA

To the Editor:—Kindly inform me whether there is any treatment for anal fistula and perianal abscesses except surgical treatment.

Oscar Gelbart, M.D., Ossining, N. Y.

ANSWER:—In every kind of anal fistula and abscess, there is an opening into the bowel with a tract leading through the soft parts to the skin. In order to obtain a cure, this opening in the bowel must be closed. Small tracts have closed as a result of inflammation. Such small openings may possibly heal spontaneously if the patient is given succinylsulfathiazole or sulfaguanidine, 3 or 2 Gm. four times a day, and, in addition, if he takes a 10 ounce water enema every day before movements.

Some surgeons have tried treatment by injection of sclerosing solutions such as sodium morrhuate. If this is done when infection is present the bacteria that are present in the bowel are apt to produce an abscess. The result is uncertain and the results with surgery properly executed are so satisfactory that there is little reason to attempt treatment by injection.

AMMONIATED MERCURY

To the Editor:—In the treatment of dermatitis of the scalp is it safe to apply a 5 per cent ammoniated mercury ointment to the entire scalp? Could such an ointment give rise to a toxic reaction? Does any pharmaceutical house supply ammoniated mercury in a water-miscible base?

M.D., Florida.

ANSWER:—Dermatologists not infrequently prescribe ammoniated mercury in 5 per cent concentration for use on the entire scalp in adults. Ordinarily the concentration is reduced for use in children. Unless the patient is sensitized to mercury, there would be no reason to expect trouble from its use, for usually the ointment is applied only for short periods and little of it is required to cover the scalp. The ointments containing mercury which are prepared by pharmaceutical houses for the market apparently are not made with water-miscible bases.

RESIN DERMATITIS

To the Editor:—Please discuss methods of prevention of contact dermatitis from a resin used in gluing plywood together called "P. R. 14" or "amberlite" made by the Resinose Products and Chemical Company, Washington Square, Philadelphia 5.

M.D., Wisconsin.

ANSWER:—In order to prevent dermatitis from resin, it is necessary to avoid contact with it, for desensitization to resin cannot be induced. If it is impractical to wear gloves during work, contact can be avoided by wearing any of the so-called chemical or invisible gloves or protective ointments that are advertised for use in industry. There are several available on the market. They serve adequately to protect the skin against the action of irritants except when it is necessary to wet the skin, for these protective preparations are usually soluble in water.

PAGET'S DISEASE

To the Editor:—Please give information on the use of aluminum acetate in the treatment of Paget's disease.

Samuel Waldman, M.D., Brooklyn.

ANSWER:—Agreement is lacking amongst authorities as to whether aluminum acetate in the treatment of Paget's disease does any real good. However, one is dealing with a chronic disease and there is sufficient evidence from reliable observers to warrant at least a trial of the drug in treating Paget's disease (Paget's bone disease or osteitis deformans).

The aluminum acetate solution is made in the following proportion:

Solution aluminum acetate.....	8 ounces
(Burrow's solution)	
Syrup of tolu.....	3 ounces
Honey sufficient to make.....	16 ounces
1 teaspoonful two or three times daily	

HERPETIC STOMATITIS

To the Editor:—I should like to supplement the answer to the query on "herpetic stomatitis" in *The Journal*, Dec. 13, 1947, page 1040. First, herpetic stomatitis is not necessarily accompanied by external lesions of herpes simplex, as the writer states; such an association is exceptional. Second, it is by far the most frequent reason for recurrent oral ulceration over a period of many years. Finally, it is almost always relieved, and sometimes actually cured, by repeated vaccination against smallpox, or perhaps better, repeated biweekly intradermal injections of smallpox vaccine suspended in saline solution. The technic is described in detail in the *Proceedings of the Staff Meetings of the Clinic, Honolulu*, for August 1944.

Harry L. Arnold Jr., M.D., Hawaii.

SOME ACTIVITIES AND IMPACTS OF THE AMERICAN BOARD OF INTERNAL MEDICINE

Chairman's Address

CECIL JAMES WATSON, M.D.
Minneapolis

In exercising the Chairman's prerogative this afternoon I wish to address the Section on certain activities and impacts of the American Board of Internal Medicine. I feel impelled to discuss this topic because of certain rather widespread misunderstandings that have arisen about the board. As one of the two co-sponsoring organizations this Section must obviously have a deep interest in the board's policies and activities; hence I am sure you will appreciate the reasons for my choice of this subject. What I shall have to say represents my own information and views as an individual member of the board; nevertheless, it is a pleasure to state that the other members have been kind enough to read this paper and approve of its being presented to you today.

The first of the misunderstandings to which I referred a moment ago relates to the constitution and degree of autonomy of the board. I find the idea commonly held that the board is a fully autonomous self-perpetuating group, answerable only to its own dictates. In fact, the board is simply the instrument of this Section and of the American College of Physicians. Its membership and policies are subject to the direction of these two agencies through the mediums of election of new members and of influence by discussion and advice. In its organization the board is guided in a general way by the by-laws of the Advisory Board for Medical Specialties, this being composed of representatives from each specialty board as well as the Council on Medical Education and Hospitals of the American Medical Association, the Association of American Medical Colleges and the American Hospital Association. It is perhaps well to note that the main responsibility for general policy formation lies with the Advisory Board.

Contrary to widespread belief that the Board of Internal Medicine has broad latitude in forming policies affecting the practice of medicine, it may be emphasized that the only function and responsibility with which it is charged is that of examination to determine fitness for certification as an internist. It is true that the training requirement for eligibility to examination has had and will continue to have a considerable impact

on the practice of medicine. It has been argued that the establishment of a training requirement is not the function of an examining board. Nevertheless, it was the will of the founders, representing this Section and the college, that such a requirement be established, and, as you know, it has been in effect from the beginning, except for those who graduated prior to 1936, since the requirements were first published late in that year. Until last year the prerequisite to examination consisted of three years of formal training and two years of practice. The board then reaffirmed its belief in this program, but at the same time relaxed the requirement in favor of longer periods of practice and shorter periods of formal, or residency, training. The new plan recognizes that a man may become a capable internist by different pathways, and it therefore allows considerable latitude in the type of program leading to eligibility for examination. There has been a good deal of unawareness of this change. I will not take time to discuss it now, but will simply point out that it has been fully described in *THE JOURNAL* (134:1399 [Aug. 16] 1947) and in the *Annals of Internal Medicine* (27:845 [Nov.] 1947).

Since the board is an examining board, it is self evident that the character of its examinations is the keystone of its structure; on this score, too, there have been some confusion and misunderstanding. The policy of the board since its incipency has been to formulate examinations intended to determine whether a candidate, if certified, might be regarded not only as an able practitioner of internal medicine but a capable consultant as well.

The comments which I wish to make on this subject have the approval of the board's committee on examinations for 1948. Dr. M. A. Blankenhorn, chairman, Dr. Alexander Burgess and Dr. Truman Schnabel. Somewhat more than two years ago the board abandoned the essay type of examination in favor of an objective and comprehensive type. I have heard it said that the board was obliged to resort to the "true-false" method of examination because of the large number of candidates. There can be no doubt about the great throng of candidates in the past two years, and in a certain sense the objective examinations used have been of "true-false" type. This term, however, is more correctly applied to an examination consisting of single statements which are true or false, a type which has not been used by the board as it is much less discriminating than the multiple choice examination. The latter was selected not merely, or even chiefly, because of the ease and speed of correction, but on the basis of proved superiority from a number of other standpoints. I may pause to remark that there appears to be relatively little general awareness, among teachers of medicine, of studies which have been documented by psychologists

From the Department of Medicine, University of Minnesota Hospital, Minneapolis.

Dr. Victor W. Logan of Rochester, N. Y., librarian of the board's Examination Committee, provided the data in the figure and in table 2. Read before the Section on Internal Medicine at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

and students of education with respect to the superior merit of properly prepared multiple choice examinations.¹ This is not to say that the ones thus far given by the board have been models of perfection. Certain deficiencies have been recognized, and a constant effort to minimize them is being made; nevertheless, I am satisfied that these examinations have been superior to the essay type. They have permitted a much broader sampling of the candidate's general knowledge of internal medicine and the basic sciences pertaining thereto; as the name implies, they have been wholly objective and the correction has been correspondingly fair and uniform, which it can never be with the long essay type. It has been argued that the multiple choice examination does not probe the candidate's ability to reason as well as the essay type. This depends largely on the character of the question, which may be devised to test nothing more than factual knowledge or experience or to provide a situation which requires considerable analysis and reasoning. The following problem is an example of the latter variety:

A physician, 76 years of age, had diabetes for many years. He received 20 units of crystalline zinc insulin daily in divided doses. He experienced sudden onset of impaired vision while

MARCH 1947

423 CANDIDATES

Frequency distribution curve of candidates' scores.

he was reading the newspaper, with transitory confusion and disorientation. There was painful sensation above the right eye and tenderness in the right supraorbital notch. The examiner's finger was not seen as it came up on the left side of the face until it reached the midline; the patient perceived it at the usual location as it came up on the right or from above or below. The right optic disk was indistinct, while the left was normal in appearance. There were no other abnormal physical observations.

It is most probable that the syndrome described was due to:

1. A retrobulbar (arteriosclerotic) hemorrhage on the right side, involving the optic and supraorbital nerves.
2. Hemorrhage from a small aneurysm of the internal carotid artery just at the circle of Willis.
3. Rupture of a craniopharyngioma (Rathke pouch cyst).
4. Thrombosis of a branch of the right posterior cerebral artery.
5. Thrombosis of the cavernous sinus.

This situation tests the candidate's knowledge of anatomy as well as his clinical experience and analytic ability. He must recognize, to begin with, that the patient has homonymous hemianopsia, which narrows the choice to either 2 or 4. On an anatomic basis alone 3 or 5 would be remote possibilities, but the candidate's knowledge of pathology and his past experience, if at all adequate, will induce him to reject them. Correct evaluation of the painful sensation above the right eye and the supraorbital notch tenderness depends on his knowledge that the supraorbital nerve is a branch of the first or ophthalmic division of the trigeminal, this division lying adjacent to the internal carotid artery, anterior to the circle of Willis and in close relationship to the optic nerve just posterior to the chiasm. This location is in good agreement with the observation of homonymous hemianopsia of the left side; hence 2 is the correct choice.

This question that I have just shown you has not been used in an examination. If it were to be used, how would the board determine whether it is too difficult or too easy? In the first place, it must be clear that the members of the board's examination committee can answer it with unanimity. If they concur on any given question and agree that it is acceptable in other respects as well, it may then be used in the next examination. But, you will say, perhaps it is still too difficult, in spite of the committee's judgment. In this connection I may assure you that the examination committee in the main leans over backward, as the saying goes, to avoid inclusion of questions that might be regarded as unfair, ambiguous, tricky or simply too difficult. Nevertheless, a further device is employed to gain more accurate judgment as to the difficulty of the individual questions and the examination as a whole. Each member of the board selects one or two capable internists in his locality who have been certified by the board for at least three years. These men, without advance notice, are requested to take the examination within a few days after the date on which it is given to the candidates. Their score and the manner in which they handle individual questions are then carefully scrutinized. If a significant number of the "guinea pigs" disagree on a question it is usually scratched, that is to say, not counted in scoring the candidates' papers. After subtraction of points for questions which have been scratched on the basis of these trial runs, the candidate's scores are calculated and plotted in the form of a frequency distribution curve. An example, that of the March 1947 examination, is shown in the figure.

The form of this curve in itself is reassuring as to the reliability of the examination. The passing score was set at 125. The individual scores of the certified "guinea pigs" are indicated. It is seen that, with one exception, they did very well. Human frailty is such that one should scarcely expect all the guinea pigs to pass in all instances, though as a rule it is gratifying to find their scores well in the upper brackets. It is of some interest to consider the factors which might have been responsible for the low score in this one instance. Perhaps the essay and oral examinations which permitted his certification several years previously dealt more kindly with him than his knowledge or experience warranted; or perhaps he had since then allowed his reading and study to lapse to such an extent that he was able to answer less than half of the objective questions. One of the advantages of the objective multiple choice examination is that it permits

1. The multiple choice comprehensive examination is now used by the Association of American Medical Colleges (Professional Aptitude Test), the Cooperative Test Service of the American Council on Education and the United States Armed Forces Institute.

a broad sampling of the candidate's knowledge of recent advances and hence of the extent to which he is striving to "keep up with the literature." It also permits the board to gain insight into the breadth of his information and experience in those disciplines and diseases which are more or less intimately related to internal medicine, such as neurology, clinical pathology, allergy, tuberculosis and syphilis. The question which was given as an example a moment ago was mainly neurologic in character. The breadth of the examination bears directly on the question of the board's impact on specialization, an important matter to which I shall return in a moment. First, however, I wish to add another point with respect to the examination itself. Further information is readily obtained as to the relative "hardness" of individual questions by reference to the performance of the upper, middle and lower thirds of the candidates, the division in thirds being based on scores for the entire examination. Thus, if it is found that 85 per cent of the upper third answered a given question correctly, as compared with 60 per cent of the middle third and 35 per cent of the lower third, this reveals that the question discriminates satisfactorily and that it may be used to advantage in a subsequent examination. If, however, 98 per cent of the upper third, 95 per cent of the middle third and 90 per cent of the lower third answer the question correctly, it is obviously too easy. The converse is true if only 35 per cent of the upper third, 32 per cent of the middle third and 25 per cent of the lower third make the correct choice. Such questions do not discriminate well and must be either discarded or altered in the proper direction if they are to be used again. The possession of a large pool of questions from which to draw permits repeated use of discriminating questions at suitable intervals. This pool, of course, is steadily replenished by questions relating to newer information, while those believed to have become obsolete are discarded or altered.

The purpose of the oral examination is to determine the candidate's clinical ability and whether his training and experience are sufficient to qualify him as a consultant in internal medicine. The members of the board assume that the candidate is well aware of this and that he elects to come up for the examination only after an ample period of preparation. Particular attention is given in the oral examination to the following attributes:

I have heard it said that the examiners ask questions about what they know, rather than what the candidates know. Obviously, however, the examiners are chosen because of an assumed broad knowledge of internal medicine, so that their questions may be expected to relate to what the candidates *ought* to know. It is axiomatic that the members of the board are careful to avoid any undue emphasis on topics of their own special interest.

There has been a gratifying correlation between the results of the multiple choice written and the oral examinations, as shown in table 2.

To turn for a few moments to certain impacts of the board, I wish to remark first on the matter of specialization. It was inherent in the establishment of specialty boards that specialization along the well established cleavage lines would be emphasized. It is not too surprising that various attempts are being made to promote further subspecialization by the formation of individual boards. The American Board of Internal Medicine has

four subspecialty committees, in cardiovascular, pulmonary, gastrointestinal and allergic diseases. I think that it is safe to say that the board feels just as strongly now as in the past that it would be undesirable to establish independent boards which would examine in these subspecialties alone and that persons who are to be specially certified in these divisions should be capable of passing the regular examination in internal medicine. If they are to have a special interest in allergic or pulmonary diseases, it is essential that their training and experience be sufficiently broad so that they will naturally consider allergic or pulmonary manifestations against the whole background of internal medicine. I believe that this statement is sufficiently obvious not to require any illustration or amplification.

There is a degree of specialization which is, no doubt, in the best interest of medicine, but beyond which more harm than good may be anticipated. It is my opinion that the policy and the type of examination of the American Board of Internal Medicine constitute a bulwark against undue specialization which ought not be overthrown.

10 plus.....	32	56

* Points above the passing score.

The question has been raised whether the specialty boards have an undesirable impact on the younger generation in medicine, in the sense that their examinations exert a leveling influence or tendency toward mediocrity. The thought has repeatedly been expressed that the boards are responsible for a regimentation which tends to prevent persons with special talent from achieving what they might in other circumstances. If this were true, it would relate more particularly to training and accomplishment in medical research. If young men with investigative talent were being lost to medical research in greater number than would otherwise prevail, this would indeed be a serious matter. I have studied this question with some care and have discussed it with many clinical investigators and medical teachers, and I feel confident that it may be answered in the negative. To those in my own school who have shown the necessary interest and zeal for research in internal medicine, the certification by the board has not been the prime objective. They have simply taken it in their stride when the time was ripe. Thus far, at least, there has been no instance in my experience in which such a person has given up a promising career in teaching and research in favor of a more remunerative practice, simply because of having become certified.

There have been, however, a great many with little or no interest in research, whose prime objective has been certification. It is safe to say that the majority of these have had more and better training than they would have had without this objective. A great many of them have gained habits of reading about disease and of investigating their patients which will further their entire careers as physicians. It has been said that unless the examination is repeated every five years or so there is no way of knowing whether a man's certification continues to be deserved. This is true, but it does not vitiate the belief that the habits gained in the training prior to the examination will maintain a great many at a higher level of thought and practice than would otherwise be probable. While there would be both interest and advantage in reexamination every five years, it is a practical impossibility, but this fact in no way detracts from the value of the initial examination.

I wish now to refer briefly to the impact of the board on the general practice of medicine. There are two particularly important aspects of this matter. The first relates to the supply of general physicians, especially for smaller communities. Again it was inherent in the establishment of specialty boards that relatively more of the medical graduates of the country would enter specialties and relatively less would take up general practice. Except for the war, it is doubtful that this would have created any significant disparity. During the war preferment was given to specialists, and this naturally provided a strong impetus to specialty training, which is residual in the salary scales of the Veterans Administration at the present time. This may be regarded as unfortunate, but no one can blame the latter agency for seeking the best trained personnel and taking advantage of certification to avoid the difficulty of making certain staff appointments under one pressure or another. Nor can it be doubted that the existence of the specialty boards and their certification has been a major factor, since 1946, in the elevation of the Veterans Hospitals to the present high plane of achievement in professional care and graduate medical education. The same may be said, in fact, of many private hospitals throughout the country.

Since the end of the war the American Board of Internal Medicine has certified 1,247 physicians. It is unlikely that a majority of these will quickly become established as consultants in large centers. Not a few have entered group or private practice in smaller communities. These men are serving as family physicians and are thus contributing materially to the first line care of the sick. Unlike many general practitioners, their time is not divided between surgery and medicine; hence they are able to consider the problems of their practice in more detail and to meet the challenge of functional disease in a much more adequate way. The magnitude of this challenge was emphasized by Dr. Wearn in his chairman's address to this Section last year; it is apparent, I am sure, that in the proper handling of this truly large segment of the physician's practice time is an essential element, and I submit that one who is first and foremost a physician is more likely to give adequate time to the functional problems than one who is striving to serve as both general surgeon and physician. Because this touches on a difficult but highly important aspect of the question of specialization, I should like to digress for a moment, to consider it in more detail. I think that we have all become increas-

ingly aware that the growth of knowledge and technics of medicine and surgery has long since outstripped the ability of one mere mortal to master and apply them to the best advantage. One may venture to predict that the next decade will find many more who have determined to build a general practice on the cornerstone of internal medicine rather than surgery. A number of institutions, including my own, are offering two year internships in training for general practice. The pattern of these consists of a year of medicine, including neurology, psychiatry and dermatology, and a second year, divided equally between obstetrics and gynecology, pediatrics and emergency surgery. Training in elective surgery is omitted entirely. A third year of assistant residency in medicine is strongly recommended, but with or without this the physician may be expected to serve as a family physician in a truer sense, rather than a general practitioner worshipping at the shrine of elective surgery. The facility of modern transportation is such that his surgical cases are readily gotten into the hands of a capable surgeon working in a fully equipped hospital. He must be determined to forego the larger income which the fees for operations would provide; if he has regrets on this score, let him read Hugh Morgan's fine essay "Professio" (*Ann. Int. Med.*, May 1948). The physician with this training and experience in general practice is admirably suited to specialization in internal medicine at a later date, should he so elect. By means of the alternate plans previously referred to, it would be unnecessary for him to take additional formal training unless he wished. During his general practice, whatever its tenure, he would not be faced by the dilemma which must be very real in the case of many general practitioners seeking membership in the American College of Surgeons; i. e., that, while it is required that a principal percentage of their practice must be surgical, a large majority of the patients for whom they accept responsibility have medical, and often functional, complaints, rather than a condition requiring operation.

In closing I should like to say that I am sure that the other members of the board view with regret, as I do, the exclusion of noncertified physicians from the staffs of certain hospitals. I feel that a duly licensed doctor of medicine should not be denied the privilege of giving his patients hospital care solely on the basis of not being certified by a board. On the other hand, the staff of any hospital ought to establish a fair mechanism for determining that none of its members, certified or otherwise, are abusing the privilege of membership. Hospital staffs ought to take a more independent view of the matter than regarding board certification as the sole arbiter of a physician's membership. Boards are bound to make mistakes, and men are bound to vary in the way they maintain their standards of practice. This being accepted, it would seem obvious that continuing merit as a physician or surgeon ought to be the only basis for membership on a hospital staff.

Thus, while the board has been the target of criticism on various scores, I am inclined to think that it has often been misdirected. I believe that no one can gainsay the really significant effect of its activities in elevating the plane of medical practice and of graduate medical education. This being accepted, then the board's only problem is one of continuous striving to uphold its standards and improve the mechanisms of its operations.

EPIDEMIOLOGY OF ENCEPHALO-
OPHTHALMIC DYSPLASIATHEODORE H. INGALLS, M.D.
Boston

During the past decade ophthalmologists have pioneered advances in the knowledge of prenatal disease which have transcended the confines of their specialty and acted as a ferment on investigations by pediatricians, obstetricians, pathologists and students of public health. The first impetus came from the observations of Gregg on the permanent consequences to infants which follow rubella of the mother in early pregnancy.¹ A drastically altered point of view of physicians toward minor disorders of gestation was the result. The implications are that the principle at work is the key to many of the structural defects characteristic of the developmental period of life.² Thus, Terry's demonstration³ that retrolental fibroplasia is a defect not merely of infants, but for the most part of prematurely born infants, challenged further study and interpretation. Krause⁴ established that the condition was generally associated with dysplasia of the brain—hence the name encephalo-ophthalmic dysplasia. Reese and Payne⁵ pointed out a significant association with single or multiple hemangiomas of the skin; all of which gives further proof to the accepted concept that ocular disease is only a part of a broader clinical pattern.

The frequency of encephalo-ophthalmic dysplasia was reported by Krause to be 1 to 4,000 total births at the Chicago Lying-In Hospital (time not stated). Assuming that 5 per cent of the total number of infants born are stillborn or nonviable, this ratio may be converted into a rate of about 0.26 per 1,000 live births. At the Boston Lying-In Hospital from 1938 to 1945, Clifford and Allers⁶ observed that in 13 per cent of 254 babies weighing less than 4 pounds (1,814 Gm.) at birth there ultimately developed the ocular sign of retrolental fibroplasia. On this basis the rate of encephalo-ophthalmic dysplasia at the Boston Lying-In Hospital for those years is computed as 1.1 per 1,000 live births.⁷ This estimate appears conservative, since missed cases of retrolental fibroplasia presumably constitute the main variable.

The association between encephalo-ophthalmic dysplasia and prematurity is clearly demonstrated by the data of figure 1, which show the distributions of the birth weights of 41 babies in whom this ocular disease

developed, and of 1,000 babies from the general population.⁸ It is evident that the incidence of the disease in any particular hospital or city will bear a relation to the numbers of premature infants born and surviving.

EPIDEMIOLOGIC IMPLICATIONS

At least two epidemiologic factors must be considered in any explanation of the significant difference in distribution of birth weights of surviving babies in whom the lesions of encephalo-ophthalmic dysplasia develop compared with viable infants of the general population. The difference may be conditioned by some characteristic of the infant host or by an alteration of the prenatal or neonatal environment. Investigation reveals that an active interplay of both these factors may be involved in production of the specific end result. An important attribute of the decidedly premature infant is the patent hyaloid artery. Terry emphasized that the terminal ramifications of this vessel nourish the retrolental site which is classically involved in the ocular disease⁹ (fig. 2). Involution of this structure is complete at about the eighth month of fetal life.¹⁰

Fig. 1.—Distribution of birth weights of 1,000 surviving babies of a general (Lying-in Hospital) population (light bars) (mean 7.25 pounds [3,289 Gm.] and standard deviation 1.2 pounds [544 Gm.]) and 41 surviving babies in whom encephalo-ophthalmic dysplasia developed (dark bars) (mean 3.3 pounds [1,497 Gm.] and standard deviation 1.3 pounds [590 Gm.]). after which disease of the tunica vasculosa lentis can hardly arise as a purely developmental defect. An analogous defect is imperforate anus, which never arises in postnatal life and assuredly cannot occur after the anal membrane has perforated in the first trimester of pregnancy.

That the placental environment may be a second factor is indicated by abundant evidence of an association between encephalo-ophthalmic dysplasia and unusual or abnormal placental conditions. Table 1 shows a strikingly increased frequency among twins and triplets, and in the presence of placental disease and hemorrhage, over expected rates for the general population. Such conditions are of course, the usual precursors of prematurity itself, and their over-all significance in relation to encephalo-ophthalmic dysplasia awaits further study. Of significance however, is the occurrence of most of the antepartum hemor-

tion to the particular disease of the baby, they should be distributed at random. They are not. The fact leads to a conclusion that antenatal hemorrhage of the mother does bear a causative relation to both defects of the baby in the groups studied.

COMMENT

The data indicating a relation between encephalo-ophthalmic dysplasia and specific conditions which constitute placental environment point to the possibility that action of the causative agent is favored by them. The associations with placenta previa, antepartum hemorrhage and eclampsia suggest the hypothesis that anoxia represents one possible causative agent. Clifford explored the relation of placenta previa and antepartum hemorrhage to asphyxia of the fetus¹³ in a postmortem

study of 11 infants, all delivered by cesarian section prior to labor. He concluded: “. . . interference with placental circulation as a result of hemorrhage from placenta previa apparently produces in the fetus an initial stage of intense blood vessel congestion that may be followed by the liberation of edema fluid, hemorrhage and even tissue necrosis.” The effects were noted to “. . . involve the organism as a whole even though symptoms referable to one part of the body . . . may dominate the picture.”

Eclampsia may produce anoxic insult to the fetus through premature separation of the placenta or infarc-

That the mortality rate rises significantly¹⁷ and the mean birth weight falls with each additional member of a multiple pregnancy is common knowledge. Newman¹⁸ ascribed the main cause of the excessive prenatal mortality of twins and supertwins to "... crowding, using this term in the broad sense to include all damaging effects due to interference of one fetus with another." Among other factors, "... there is competition between the fetal blood vessels of the two individuals (3, 4, or 5 in the cases of higher one-egg sets) for a placental area adequate for only one individual." Furthermore, "... a premature infant whether a twin or singleton is far more delicate and more easily injured at birth than a full-term baby"—in other words, the premature baby represents a susceptible host.

PRINCIPLES OF A PROGRAM FOR PREVENTION

Any program for prevention of a disease rests primarily on an understanding of causative factors. The hypothesis that sublethal oxygen deprivation is a causative agent for encephalo-ophthalmic dysplasia can be critically tested by direct methods for the determination of the oxygen saturation of maternal and fetal blood and correlating low values—particularly those obtained during periods of hemorrhage, toxemia or difficult labor—with the subsequent development of disease. If the hypothesis is confirmed, measures directed toward the maintenance of maternal-fetal oxygen saturation during the antenatal period of stress are indicated. Since the agent of disease (anoxia) is only one of three interacting factors productive of disease, the other two (host and environment) must be the object of general study and preventive measures. These are already the general objectives of modern obstetrics, namely, maintenance of a favorable placental environment, permitting the orderly intact development of the fetus beyond that stage of relative susceptibility which characterizes prematurity.

SUMMARY

Epidemiologic evidence is presented indicating that the production of encephalo-ophthalmic dysplasia results from the interaction of factors related to the fetal host and to an unusual or abnormal placental environment. One such factor in the fetus is the presence of the tunica vasculosa lentis until the eighth month of fetal life. After involution, disease of the tunica vasculosa lentis can no longer arise as a purely developmental defect. The importance of environment is suggested by high rates for multiple births, toxemia of pregnancy, placental diseases and hemorrhages among mothers of 41 babies in whom encephalo-ophthalmic dysplasia developed. An etiologic relation between antenatal hemorrhage of the mother and disease in the child is indicated by the occurrence of most of the hemorrhages in the fifth, sixth and seventh months of gestation. Significance of this timing is indicated by contrast with that of a similar phenomenon observed earlier in pregnancy among mothers of monoglot babies. Sublethal anoxia is hypothesized as a principal agent in the production of encephalo-ophthalmic dysplasia, because of the relationships to placenta previa, antepartum hemorrhage and eclampsia.

ABSTRACT OF DISCUSSION

DR. WILLIAM C. OWENS, Baltimore: Dr. Ingalls emphasized the association of retrolental fibroplasia with prematurity. I am in complete agreement with this observation. In my experience the disease has developed in premature infants. I encountered the greatest incidence in premature infants weighing 3 pounds (1,361 Gm.) or less at birth. Dr. Ingalls has suggested that antenatal anoxia, resulting from an abnormal placental environment associated with multiple pregnancy, placental hemorrhage or toxemia of pregnancy, may be a causative factor in the disease. However, as Dr. Ingalls stated, these abnormal conditions are "... the usual precursors of prematurity itself, and their over-all significance in relation to encephalo-ophthalmic dysplasia awaits further study." Since retrolental fibroplasia occurs principally, if not entirely, in premature infants, the higher incidence of these factors in cases of the disease may be related to the prematurity alone and not specifically to the occurrence of retrolental fibroplasia. The incidence of these abnormalities of the placental environment in the cases of retrolental fibroplasia shown by Dr. Ingalls in table 1 is not greater than the incidence of these factors in cases of prematurity as a whole, as reported by Anderson and Lyon, and by Eastman. Therefore it is not clear whether the postulated causative factors are not related generally to prematurity rather than specifically to retrolental fibroplasia. My observations on the clinical course of retrolental fibroplasia do not lend support to Dr. Ingalls' postulate as to the significance of the persistence of the hyaloid system. For the past three years, Dr. Ella Uhler Owens and I have been routinely examining the eyes of the infants in the premature nursery of the Johns Hopkins Hospital. We have observed the onset, course and development of the final picture of retrolental fibroplasia. None of the infants had retrolental fibroplasia at birth. The disease was not related to persistence of the hyaloid system. Early postnatal examinations of the eyes revealed normal fundi. The earliest change observed was progressive angiomatous dilatation of the retinal vessels, followed by the development of extensive grayish retinal edema and detachment. The vitreous became cloudy. The retrolental membrane was formed by the extension across the retrolental space of fusing peripheral portions of the swollen grayish retinal detachments. The vessels in the retrolental membrane had their origin from retinal vessels and not from vessels associated with the embryonic vascular sheath of the lens. In most cases the active stage of the disease subsided gradually. In some eyes the activity subsided before a complete membrane was formed behind the lens. Usually bands simulating retinal folds extended through the vitreous to localized areas of retinal detachment. New-formed vessels arising from the retina were visible in the folds.

DR. EVERETT KINSEY, Boston: Dr. Ingalls' interesting paper on the epidemiologic aspect of encephalo-ophthalmic dysplasia has been concerned chiefly with the possible causation of the ophthalmic dysplasia, rather than with that of any accompanying mental disorder. We, at the Massachusetts Eye and Ear Infirmary, prefer to call the disease retrolental fibroplasia, because we believe that there is insufficient evidence, in our cases at least, of mental retardation to justify the name encephalo-ophthalmic dysplasia. For instance, in 150 cases which are being followed up currently, in less than 20 per cent are there signs of mental disorder. To be sure, further psychological studies are necessary in borderline cases before a final evaluation can be made. Therefore, I shall use the term retrolental fibroplasia in this discussion. Dr. Ingalls has pointed to the possible importance of the prenatal environment in the production of retrolental fibroplasia, as exemplified by the high rates in multiple births, toxemia of pregnancy, placental diseases or hemorrhages among mothers of babies who subsequently have this condition. He calls attention further to the etiologic relations between disease of the mother and disease in the child, as indicated by the occurrence of hemorrhages during the sixth, seventh and eighth months of gestation. There are two points I would like to make in this connection. First, such factors as multiple births and placental diseases are in themselves frequent causes of prematurity. Since the incidence

18. Newman, H. H.: Multiple Human Births: Twins, Triplets, Quadruplets and Quintuplets, American Association for the Advancement of Science Series, New York, Doubleday, Doran & Company, Inc., 1940.

of retrolental fibroplasia is highest among infants born prematurely, it follows that the reasoning employed by Dr. Ingalls would apply equally well to any condition of the mother which is associated with premature birth. To draw any deductions concerning causation from this kind of information, one must be certain that the incidence of the disease in infants premature because of multiple birth, for instance, is significantly different from the incidence in infants born prematurely as a result of some other condition, e. g., spontaneous delivery. Dr. Ingalls pointed out that a conservative estimate of the incidence of retrolental fibroplasia at the Boston Lying-In Hospital was 15 per cent, in babies weighing less than 4 pounds (1,814 Gm.) at birth. Percentage incidence figures are always subject to variation, depending on methods used in calculating them. A detailed study of the incidence of this disease from the same hospital by our group would suggest that this figure is low.

DR. INGALLS, Boston: A congenital origin is established when the ocular disease is observed at birth or in the immediate neonatal period. Such babies who show the congenital disease are usually those born at term. The ratio of premature to term births, about 1 to 7 when the condition was recognized during the first month of life, showed a complete reversal after the third month to about 18 to 1. The differences may be explained in Terry's observation, confirmed by the testimony of those who spoke today, that it takes considerable time for some of these ocular changes to take place. If several months are required for the retrolental membrane to manifest itself, then the low incidence of ocular lesions in premature infants and the high incidence among full term infants suggest that

the causative agent acts generally about the time the premature group is born and, therefore, well before birth for the term group. To determine the significance of antenatal hemorrhages, it was said that more data are needed on antenatal hemorrhages among premature babies who did not have encephalo-ophthalmic dysplasia for comparison with hemorrhages in babies in whom it did develop. That is true, but, to produce a fourfold table, four types of data are really needed: antenatal hemorrhage followed by ocular disease, antenatal hemorrhage not followed by ocular disease, no antenatal hemorrhage followed by ocular disease and no antenatal hemorrhage not followed by ocular disease. The results could be submitted to a chi square test, which, however, is only one method of determining significance. Another method was used in this present study, based on the time at which antenatal hemorrhages occurred among mothers of babies in whom encephalo-ophthalmic dysplasia developed, as compared with the time of antenatal hemorrhages among mothers with babies having mongolism. If the time of bleeding bore no relation to disease of the baby, the hemorrhages would expectedly occur at random. They did not.

As for the term "encephalo-ophthalmic dysplasia," I have borrowed it from Krause of Chicago. It seems to me that he has made a real contribution by drawing attention to the necessity for study of the whole child. A good example was also set by Reese and Payne, who found a significant association (about 15 per cent) of the condition with hemangiomata. Likewise, a 20 per cent association of any condition with mental retardation is probably significant. It certainly makes it worth while to study the whole child.

GENERAL PRACTITIONERS SESSION

TUMORS OF THE NECK

FRANK H. LAHEY, M.D.
Boston

Tumors of the neck are important to discuss because they are not uncommon. Because of the fact that malignancy is not rare in them it is important to determine their character as early as possible; the need to know their origin and character is not far removed from that of tumors of the breast. Exclusive of the lipomas of the neck, which can occur anywhere in the neck and can usually be diagnosed by their consistency and demonstrable lobulation, there are almost no tumors of the neck which should not either be promptly biopsied or removed after discovery. I know of no other tumor than lipoma which can make one blush more for having forgotten it in considering the diagnostic possibilities in superficial tumors.

The diagnosis of tumors of the neck can be extremely simple or so obscure as to make their final diagnosis possible only by exploration and biopsy, and since many of the malignant tumors of the neck will prove to be radiosensitive lymphomas, microscopic demonstration of this character should not be delayed. Dr. Hugh F. Hare, head of the Department of Radiology, The Lahey Clinic, has recently demonstrated¹ that of 181 patients proved to have lymphomas and regularly treated with roentgen rays, 29 per cent are alive and well over five years without recurrence, a point of no small importance in the early detection and treatment of these tumors.

To make the discussion of tumors of the neck orderly, my associates and I have always classified them into midline tumors and cysts, practically all occurring as single tumors, laterally located tumors and single and multiple tumors (table 1).

These are the common tumors with which my associates and I have had to deal. I have omitted consideration of those conditions related to trauma, the extremely rare air cyst which the patient can blow up at will, pneumatocele, of which we have had 1 case, large esophageal diverticular sacs, which the patients can fill and demonstrate (rare), and the acute inflammatory lesions, such as deep cervical abscesses. Ludwig's angina and also the uncommon gummatous masses in the neck.

Midline tumors and cysts can be disposed of without too much discussion, since, except for the occasional inflammatory submental mass and dermoid, they are related either to the thyroid itself or to the developmental descent of this gland from the back of the tongue to its normal place on the upper tracheal rings.

Of the midline cysts and tumors the most dramatic as well as the rarest is the lingual thyroid and the commonest is the thyroglossal cyst. Each is the result of developmental failure, in the lingual thyroid the failure of the thyroid to descend and in the thyroglossal cyst the failure of the thyroglossal tract to close.

Lingual thyroids are supra, intra and infra in location in relation to the back of the tongue, at which point their origin is represented by the foramen caecum. We have had three of these unusual tumors, one supra-lingual and two intralingual thyroids, but no infra-lingual thyroids.

There is little to be said about the diagnosis of these tumors, since their consistent location always at the same point on the back of the tongue marks them as lingual goiters. There would be no excuse for including these rare tumors in a discussion of tumors of the neck if it were not for the fact that, as shown in figures 1 and 2, they show themselves as tumors of the neck by roentgenologic examination and as such must be considered in the diagnosis of tumors of the neck. They force themselves on the patient's attention by their gradual enlargement, finally, to the degree

Read before the interim meeting of the American Medical Association, Cleveland, Jan. 8, 1948.

1. Hare, H. F.; Mulry, W. C., and Sornberger, C. F.: Lymphoid Tumors, Radiology, 50: 506-514 (April) 1948.

that they interfere with food intake and so demand the consideration of their removal.

There are only two points to be mentioned in relation to the removal of lingual goiters. Lingual goiter usually represents all of the thyroid tissue which the patient has. Before its removal is undertaken, the surgeon will save himself embarrassment and possible criticism by explaining this to the patient and his family and informing them that following the operation it will be necessary for the patient to take thyroid the rest of his life.

Because of the location of the lingual goiter on the back of the tongue and possible apprehension of one's ability to control the bleeding expected to occur with such a vascular tumor as a thyroid tumor is known to be, and in such an inaccessible location, the operative approach to such a tumor could be selected as through

the neck, beneath the chin and through the tongue. We have had no experience with infralingual goiters of this type in which this approach might be considered but for intralingual and supralingual goiter, the approach through the mouth will prove simple and in no way troublesome. With traction stitches on the lateral aspects of the back portion of the tongue, with an intratracheal tube in place and with the pharynx packed to prevent blood from being sucked into the lungs, these tumors can be removed through the mouth and the bleeding from them controlled without any great difficulty.

The two types of swellings in the neck related to the thyroglossal tract are the pyramidal thyroid lobe (fig. 3) and the thyroglossal cyst (fig. 4).

The pyramidal lobe of the thyroid, located as it most often is just to the left of the thyroid cartilage and, when completely developed, extending from the thyroid isthmus to the hyoid bone, will interest us as a tumor of the neck only as it occurs in patients who have had

subtotal thyroidectomies performed for exophthalmic goiter in the course of which operations the pyramidal lobe of the thyroid has not been removed. Every one who has had any considerable experience with the surgical treatment of hyperthyroidism has many times

Fig. 1.—This illustration shows definitely the shadow of an intra-lingual thyroid (from S. Clin. North America, p. 487, June 1947).

seen the small pyramidal lobe of the thyroid overlooked in the thyroidectomy and not removed. When this pyramidal lobe, preoperatively so insignificant, is not removed in the subtotal thyroidectomy for active hyperthyroidism, it can so enlarge postoperatively from hyperplasia that it can be seen and felt as an unsightly finger-like tumor mass extending from the level of the

Fig. 2.—This illustration shows the specimen of the intralingual thyroid removed (from S. Clin. North America, p. 487, June 1947).

thyroid isthmus to the level of the hyoid bone and resting on the left plate of the thyroid cartilage. One cannot fail to recognize enlarged pyramidal lobes of the thyroid, because of their location and because of their firmness due to the hyperplasia and tissue regeneration

in them, as the thyroid still attempts in the remaining thyroid tissue to respond to the continuing influence of the pituitary-stimulating thyroid hormone.

These tumors are often extremely disfiguring, standing out as they often do on the neck as unsightly sausage-like longitudinally placed tumors. They are

Fig. 3.—In this illustration of recurrent hyperthyroidism (showing the scar of the previous operation), in the midline is shown a remnant which represents hyperplasia in an unremoved pyramidal lobe.

easily removed by reelevating the cutaneous flap, and in their removal it is unnecessary to remove central sections of the hyoid bone and follow them up to the base of the tongue, as is necessary in the removal of thyroglossal cysts and tracts.

Since the thyroglossal tract, representing the embryologic remnant of the fetal thyroglossal duct, extends from the isthmus of the thyroid to the foramen caecum

However, the most consistent location at which these cysts occur is slightly to the left of the midline and opposite the notch in the thyroid cartilage. They are commonest in children, but can and do delay their appearance until adult life. They have often spontaneously ruptured or have been incised after infection of the cyst (fig. 5).

We have now operated on three hundred and nineteen of these cysts and have learned, as has every one dealing with them surgically, that, if one wishes to avoid recurrences following their removal, not only must the cyst be removed but the central section of the hyoid bone must also be removed and any continuation of the thyroglossal tract followed up to the base of the tongue and removed also. This radical removal, first proposed by Sistrunk,² has never failed to remove the tract entirely and result in permanent relief of the condition in my experience. There is only one warning to be uttered in connection with this operation, and one I would not feel necessary to mention if I had not seen the unsightly results of its employment, that is that never should the incision for the excision of thyroglossal cysts be made in the longitudinal direction, but always in the transverse direction. If made in the longitudinal direction it will result in a checkrein-like scar, which is almost impossible to overcome except by means of a free graft.

TABLE 2.—Lateral Discrete Tumors of the Neck

Inflammatory salivary gland swelling with stone in the submaxillary duct
Mixed tumors of the submaxillary gland
Carotid body tumors
Branchial cysts
Neurofibromas
Discrete parathyroid malignant condition
Discrete aberrant thyroids
Discrete Hodgkin's disease
Discrete lymphosarcoma
Discrete primary carcinoma of the neck (branchial tract origin)
Discrete tuberculous cervical nodes
Discrete adenomas of the thyroid
Lipomas
Lateral dermoid cysts

Single discrete adenomas of the thyroid can occur at any level of the thyroglossal tract, but are almost never seen outside the lateral lobes or isthmus of the thyroid gland. They are not uncommon in the isthmus of the thyroid, but are usually small here, since if they attain any size they must encroach on the lateral lobes and occupy that portion of the thyroid gland.

In discussing the diagnosis of discrete lateral tumors of the neck, I would like to state, as a result of my own considerable experiences with them, that it is impossible in most of these cases to do more than state one's suspicion of what the tumor will prove to be, setting down the different types of tumors and cysts that need to be considered. No one who has had much experience with removing tumors of the neck can deny that what was thought might prove to be a tense branchial cyst has turned out to be a carotid body tumor; what was thought might be a carotid body tumor has turned out to be a discrete malignant growth of parathyroid origin, a discrete lateral aberrant thyroid mass or, for that matter, any one of the discrete laterally located tumors of the neck with the exception of discrete adenomas of the thyroid and dermoid cysts included in this list.

2. Sistrunk, W. E.: Technique of Removal of Cysts and Sinuses of the Thyroglossal Duct, *Surg., Gynec. & Obst.* 46:109-112 (Jan.) 1928.

Fig. 4.—This is a typical thyroglossal cyst. Although it appears to be in the midline, it actually is just to the left of the notch in the thyroid cartilage (from S. Clin. North America, p. 488, June 1947).

on the back of the tongue at the junction point made by the circumvallate papillae, one may observe a thyroglossal cyst at any level between these two points, in the floor of the mouth at the level of the notch in the thyroid cartilage or at the level of the thyroid isthmus.

In discussing the diagnosis of the discrete laterally located tumors of the neck, one can only suggest the features frequently observed in connection with them and at the same time admit that, in spite of this, surprises will occur when the tumors are exposed and removed and the pathologic report returned.

An enlarged salivary gland, usually secondary to a calculus within the salivary duct, is not difficult to distinguish, particularly because, with one finger in the mouth and the other over the region of the salivary gland, its location beneath the angle of the jaw, characteristic shape, the history of change in size and the presence of a calculus demonstrable by the roentgenogram or palpable through the floor of the mouth will generally make it possible to be rather certain of the diagnosis.

When chronic enlargement of one salivary gland has existed over a considerable period of time as the result of the presence of a salivary calculus, the stone may usually be excised through the mouth from its position in the submaxillary duct beneath the mucous membrane. If this does not immediately result in diminution and disappearance of the submaxillary swelling, the entire gland should be removed externally.

Fig. 5.—This illustration shows a thyroglossal cyst which has ruptured and drained, with the granulation at the point of draining. The lower level in the midline of this thyroglossal cyst as compared with the more common level near the notch of the thyroid cartilage may be seen (from *S. Clin. North America*, p. 489, June 1947).

Mixed tumors originating in the salivary gland are likewise rather readily diagnosed, because of the fact that they can be similarly palpated as arising in the submaxillary gland by combining external palpation with internal palpation by means of a finger in the mouth.

Two of the tumors of the neck which will not infrequently require differentiation are carotid body tumors (figs. 6 and 7) and branchial cysts (figs. 8 and 9). They are frequently located at about the same level. Branchial cysts are often so tensely filled with fluid that their consistency deceives one into thinking that they are tumors, and the differential diagnosis between the two types of tumors is not easy.

There are certain features of each, however, which will aid one in at least being reasonably suspicious of the diagnosis. It is to be recalled that the course of a branchial sinus, from which a branchial cyst arises

(fig. 10), is from a point just in front of either sternomastoid upward beneath the skin, beneath the belly of the digastric muscle to enter the pharynx at the region of the tonsil. Unlike carotid body tumors, the course of a branchial sinus is extremely superficial, directly beneath the skin, until it reaches the level at which it

Fig. 6.—This illustration shows a carotid body tumor, with its tendency to extend beneath the angle of the jaw and to grow inward and not outward as seen in the illustration of the branchial sinus (from *S. Clin. North America*, p. 494, June 1947).

passes beneath the belly of the digastric muscle. It is obvious, then, that the tendency of thyroglossal cysts will be to enlarge outward, in contradistinction to that of carotid body tumors to enlarge inward, arising as they do, deeply in the neck, and situated as they are, at the notch made by the external and internal carotids.

Rarely do branchial cysts extend under the angle of the jaw as do carotid body tumors. Because of their superficial location, branchial cysts are movable, and whether or not they are cysts can be determined by the exploratory introduction of a small caliber needle.

Fig. 7.—This also is a carotid body tumor and has the same characteristics, inward growth, as shown in figure 6.

Branchial cysts, as shown in figure 11, can attain large dimensions; they are often rather disfiguring and, of course, because of their epithelial elements, possess always the danger of malignant degeneration, although the percentage of malignant conditions in branchial cysts is relatively low. Since they are superficially

located, their removal is not difficult or dangerous and, with good exposure and dry fields, can be accomplished successfully with relatively little danger to any important structures except the large vessels, the hypoglossal nerve and, at times, the spinal accessory nerves.

Fig. 8.—This is a photograph of a patient with a branchial cyst, showing the tendency of this type of tumor, as discussed in the text, because of its superficial location, to grow outward and downward (from *S. Clin. North America*, p. 491, June 1947).

Carotid body tumors are not common tumors. In a recent article reporting our experiences with eighteen carotid body tumors,³ Warren and I reported that we had found that only three hundred carotid body tumors had been reported in the literature.

Carotid body tumors, arising as they do from the carotid gland in the notch made by the junction of the external and the internal carotids, are as stated, deeply located tumors. Unlike branchial cysts, carotid body tumors enlarge not outward but inward and upward.

Fig. 9.—This also is a photograph of a patient with a branchial cyst, showing in this case that the distinguishing feature of external enlargement is not as apparent as in figure 8, again demonstrating that, regardless of the distinguishing features of tumors of the neck, differentiation of them will often be difficult.

They are characterized not only by their deep location but by extending upward toward the base of the skull behind the angle of the jaw, and, while, as shown in figure 12, they do produce a swelling on the neck, the

greater part of the enlargement is not outward. In the aforementioned article on carotid body tumors, attention is called to a feature of carotid body tumors which frequently may not be appreciated unless one has had some experience with them; that is, the tendency of certain carotid body tumors to bulge into the pharynx to such a degree that they can interfere with swallowing. In 2 of the patients on whom we operated for carotid body tumors, such was the intrapharyngeal bulging as the result of the pressure of these tumors that their removal became an urgent necessity, because of the fact that the patients were unable to swallow an adequate amount of food.

Another feature to be remembered in carotid body tumors is the fact that, unlike other tumors of the neck, they cannot be dislocated downward. Since they arise in the carotid notch, it becomes obvious that they cannot be made to move downward by pressure. Still another diagnostic point in carotid body tumors

Fig. 10.—This photograph of a branchial sinus injected with iodized poppy seed oil is shown to demonstrate the course of the branchial tract and its superficial location. This was a complete branchial sinus in which the injection could be done from the point of exit in front of the sternomastoid to the point of entrance into the pharynx.

is that their deep origin just beneath the mucous membrane of the pharynx can frequently be demonstrated by bimanual palpation, with two fingers, one finger in the mouth, pressing on the side of the pharynx, and the other on the neck, beneath the angle of the jaw. One can also not infrequently determine the origin of these tumors when they are palpated bimanually by demonstrating the relationship of the tumor to the bimanually palpated common, external and internal carotid vessels.

The percentage of malignant conditions occurring in carotid body tumors has been placed at various levels by various authors, ranging from 20 to as high as 50 per cent. In the series of 18 cases recently reported by Warren and me there were no malignant conditions, and since that time two additional carotid body tumors

3. Lahey, F. H., and Warren, K. W.: Tumors of the Carotid Body, *Surg., Gynec. & Obst.* 85:281-288 (Sept.) 1947.

have been removed in which there were no malignant conditions.

Because carotid body tumors tend to enlarge and may ultimately require removal because of pressure, because in a definite percentage, even if they are small, malignant degeneration will occur, it is my opinion that all carotid body tumors should be excised if possible. When, however, the carotid body tumor surrounds all three vessels, as shown in figure 13, necessitating the ligation of all three vessels for its removal, I do not believe that its removal is justifiable. In my hands, the mortality of this procedure has been 33 per cent, which I believe is higher than the incidence of malignant degeneration. In the cases in which ligation of all three vessels is necessary I believe that the tumor should not be removed. When, however, malignant degeneration has been demonstrated or when the size of the tumor and its pressure on the pharynx with its increased size are such as to interfere with swallowing and when, in addition, it becomes evident that the tumor can be removed only by the ligation of all three vessels, I believe that a preliminary low ligation of the common carotid by the infolding plan devised and practiced by Dr. James L. Poppen in the

Fig. 11.—This is a photograph of a large branchial cyst extending down toward the shoulder. This is of unusual size and of unusual location.

Neurosurgical Department of the clinic, in the management of intracranial aneurysms, is the plan to be employed (fig. 14). With the common carotid infolded and ligated for six weeks, particularly when afterward heparinization is done to avoid thrombosis, later removal with ligation of the external and internal carotids will prove distinctly less hazardous.

Lateral aberrant thyroid tissue,⁴ arising from the ultimobranchial bodies, as shown diagrammatically in figure 15, can be made up of multiple nodules or of a single discrete nodule, as shown in figure 16. One must have in mind that any laterally located solid discrete tumor of the neck can, on microscopic examination, prove to be a lateral aberrant thyroid, either benign or malignant. If a laterally located single tumor of the neck proves to be an aberrant thyroid, the remainder of the neck should be carefully searched for other small aberrant thyroid tissues and removed by radical complete dissection. If the discrete lateral aberrant thyroid tumor proves to be malignant papillary adenocarcinoma, a radical dissection of the neck on that side should be carried out.

Neurofibromas of the neck, as shown in figure 17, can occur at any level and at any location on the neck and can arise from any of the nerves in the neck. In figure 18 is shown one which occurred beside the pharynx, and in it the deviation of the esophagus filled

Fig. 12.—This is still another photograph of a carotid body tumor, to indicate that even though the carotid body tumor may be at a location lower than the angle of the jaw, due to the fact that the carotid notch is lower, the tendency of the tumor is still to project inward and not to enlarge outward as do most of the branchial cysts.

with barium sulfate can be seen. They are discrete and firm, and the final diagnosis in these tumors can be made only with a pathologic report. They are of a low grade of malignancy; they tend to recur locally

Fig. 13.—In this photograph of a removed carotid body tumor, it can be seen that the tumor had surrounded all three branches of the carotid, the common, the external and the internal, so that they were enveloped and removal required ligation of all three vessels. This ligation of all three vessels in my actual experience has resulted in a mortality of 33 per cent and in my opinion should never be done. It is in enveloping carotid body tumors such as shown in this illustration that removal is not advised.

and should be removed radically, and one should take care that they are removed completely and intact.

4. Lahey, F. H., and Ficarra, B. J.: *The Lateral Aberrant Thyroid*, Surg., Gynec. & Obst. 82:705-711 (June) 1946

Three types of tumors have occurred, in my experience, of parathyroid origin—parathyroid cysts, parathyroid adenomas and discrete lateral malignant growth of parathyroid origin. Parathyroid cysts have been seen up to the size of a horse chestnut and parathyroid adenomas, likewise, up to the size of the horse chestnut.

Fig. 14.—In this illustration (supplied by Dr. James L. Poppen of the Neurosurgical Department of the Clinic) is demonstrated the method of infolding the common carotid vessel and then ligature to avoid (1) cutting of the ligature and (2) the production of thrombosis. This is the method that Dr. Poppen has employed in dealing with carotid ligation in intracranial aneurysms.

Parathyroid cysts and parathyroid adenomas have occurred in direct relationship to the thyroid gland and have been seen located posterior to it. The rare malignant growths of the neck of parathyroid origin which

Fig. 15.—In this illustration (A, B and C) are shown the three types of aberrant thyroid which I have found in a series of 47 patients with this lesion on whom I operated and reported in an article on this subject. In C is shown the typical discrete tumor of aberrant thyroid origin.

I have seen have been of considerable size and not related to the thyroid itself. They have been discrete laterally located movable tumors of the neck, and the diagnosis has been made in every case only with the pathologic report.

Lymphosarcoma has occurred, in my experience with tumors of the neck, as a discrete tumor and as Hodgkin's disease. Discrete primary carcinoma of the neck arising in the branchial tract has likewise occurred in my experience, and all of these tumors have been diagnosed solely on the basis of the pathologist's report.

Discrete tuberculous cervical nodes have occurred in my experience, but much less commonly than in the past, when this disease was particularly common in children, prior to almost routine tonsillectomy in children and prior to inspection of milk herds for tuberculosis. Tuberculous adenitis of the cervical nodes most commonly occurs in the region drained by the tonsils. The nodes most commonly involved discretely are those just below the angle of the jaw and in front, beneath or behind the sternomastoid muscle. While tuberculous cervical adenitis can occur as a discretely involved gland, it does not usually occur in a single gland. The diagnostic feature which will be helpful in one's sus-

Fig. 16.—This is a single discrete tumor of the neck, of lateral aberrant thyroid origin with carcinomatous degeneration. In comparing this photograph with one of a patient with a branchial cyst one can easily see how difficult it is to differentiate some of the tumors of the neck (from S. Clin North America, p. 493, June 1947).

picion of the diagnosis is the fact that in any tuberculous gland which has reached the size of a horse chestnut rarely will caseation be absent. In the presence of caseation rarely will calcium deposits be absent which can be demonstrated by the roentgenogram, and this suggests the diagnosis of tuberculous lymph node.

If a tuberculous node of the neck does occur as a discrete involvement of a single node or set of nodes, excision followed by radiation is a most satisfactory form of treatment. It is to be recalled, however, that the spinal accessory nerve passes beneath the sternomastoid at this point where discrete tuberculous glands of the neck are so likely to occur, that is, behind the middle portion of the sternomastoid muscle, and that, in dissection of the tuberculous node here, this nerve is in danger. It is to be recalled also that the spinal accessory nerve innervates the trapezius, which by scapular rotation provides the last 90 degrees of abduction of the arm, and that injury to it results in serious loss of motion and function of the arm.

Discrete adenomas of the thyroid should never be difficult to diagnose, since, with few exceptions, that is,

those adenomas extruded from the thyroid, the discrete tumor can be palpated as arising in one of the lobes of the thyroid. There is one distinguishing characteristic of a tumor, discrete or multiple, arising in the thyroid gland, and that is the fact that it ascends and descends with swallowing. The only other tumor occurring at this location that I know of which ascends and descends with swallowing is the fibroma of the esophagus.

Discrete adenomas of the thyroid with their relationship to thyroid malignancy (table 3), in my opinion, should all be removed, since the mortality in removal of these tumors should be zero.

It is to be recalled that inclusion cysts of the neck (dermoid cysts) can occur at any level (figs. 19 and 20), from the back of the tongue to the level of the clavicle.

Fig. 17.—A neurofibroma removed from the neck in the region of the pharynx.

TABLE 3.—Incidence of Malignancy in Thyroid Adenomas *

Year	Total Thyroid Tumors	Malignant Conditions, Percentage
1926.....	443	3.6
1927.....	501	4.0
1928.....	526	10.8
1929.....	655	7.3
1930.....	574	4.3
1931.....	504	3.5
1932.....	495	3.2
1933.....	426	3.5
1934.....	495	5.0
1935.....	433	3.5
Total.....	5,052	

* Because of the statements which are being made of late that there is little danger of malignancy in adenomas of the thyroid, its incidence over a ten year period in 5,052 cases of tumor of the thyroid is recorded.

Attention has been called to the fact that lipomas can occur in any portion of the neck, but the possibility of this diagnosis should not be forgotten in considering any tumor of the neck not of solid consistency.

The lateral multiple tumors of the neck, consisting of Hodgkin's disease, tuberculous cervical adenitis, multiple aberrant thyroid, cystic hygromas of the neck

Fig. 18.—In this illustration may be seen the outline of the shadow of the neurofibroma beside the pharynx, as indicated by arrows.

Fig. 19.—This diagrammatic illustration demonstrates the levels at which inclusion cysts (dermoids) can occur, in the back of the tongue to the level of the clavicle, in order of their frequency of occurrence in my experience.

and multiple colloid adenomatous goiters, present particularly difficult diagnostic problems.

I do not believe that it is possible to distinguish, with any definite certainty, Hodgkin's disease from tuberculous cervical adenitis by any other means than biopsy. When Hodgkin's disease occurs in multiple

Fig. 20.—A dermoid cyst in the midline beneath the jaw.

locations, one can be suspicious of it, when the character of the glands in Hodgkin's disease is typical that is, multiple movable grapelike structures without

Fig. 21.—A cystic hygroma of the neck, beneath the jaw. Again, this demonstrates how difficult it is to differentiate many of the cysts or tumors of the neck. From its location, this could easily be a tumor of the submaxillary gland (from S. Clin. North America, p. 499, June 1947).

inflammatory reaction; one may be suspicious of Hodgkin's disease, but the final differentiation between tuberculous nodes of the neck, lymphosarcoma and

the various other tumors of the neck, either single or multiple, can be made with certainty only by the removal of a node and on the basis of the pathologic report. While multiple glands of Hodgkin's disease, when it is diffuse in character, are not usually fused together, as inflammatory glands seen with tuberculous cervical adenitis often are, I have seen tuberculous cervical adenitis occur in all forms and types and have never attempted to do more than consider the possibility of both lesions and settle the final diagnosis by biopsy.

Multiple aberrant thyroids have in most instances a feature which is helpful in distinguishing them from

Fig. 22.—This is a photograph of an intrathoracic goiter, showing the extrathoracic and intrathoracic portions (from New England J. Med., 236:60 [Jan. 9] 1947).

other multiple glandlike tumors of the neck; that is, they tend to occur as a lateral chain running longitudinally up and down in front of the sternomastoid, in close relationship to the internal left jugular vein. They may occur as a small discrete chain of glandlike structures; they may occur as a chain of small glandlike structures with an occasional large glandlike mass, or they may occur, as previously stated, as a single discrete and large lateral aberrant thyroid tumor.

Little need be said about the diagnosis of multiple colloid adenomatous goiter, since the diagnostic features which attach themselves to the discrete adenoma of the thyroid are likewise true of multiple adenomas of the

thyroid; that is, their origin within the thyroid and the fact that they ascend and descend with swallowing. These features should in practically all cases make it possible to settle when multiple tumors of the neck are multiple adenomatous goiters and to distinguish them from the other lesions producing multiple tumors, aberrant thyroid, tuberculous cervical lymph nodes, Hodgkin's disease or multiple lymphomas.

Cystic hygromas of the neck, with their diffuse character and their cystic consistency, in most instances are not difficult to diagnose (fig. 21).

In discussing tumors of the neck one should not fail to mention the differential diagnosis of the low-lying tumors of the neck, particularly those that either extend into or emerge from the supraclavicular space, the commonest of which is intrathoracic goiter. This is the type of goiter which is largely intrathoracic, with its topmost portion projecting up through the upper thoracic strait, so that it can be palpated

Fig. 23.—This roentgenogram demonstrates the deviation of the trachea which occurs with the intrathoracic goiter shown in the previous illustration, showing the deviation of the trachea to the left or to the right, which occurs in the typical adenomatous thyroid which has descended into the mediastinum (from *New England J. Med.*, 236:60 [Jan. 9] 1947).

above the clavicle in the root of the neck. Intrathoracic goiter is the commonest of all the low-lying tumors of the neck which extend into the mediastinum, and has several rather typical characteristics. Again, as is true of all tumors of the thyroid, it is the only tumor in the neck, exclusive of the fibromas of the esophagus, an example of which is shown in figure 22, which ascends and descends with swallowing. Since intrathoracic goiters are oftenest discrete adenomas of the thyroid which have descended into the mediastinum with their upper surface showing above the clavicle and arising usually in a lateral lobe, they will deviate the trachea characteristically either to the right or the left, as shown in figure 23. They are practically the only tumor in the lower part of the neck which curves the trachea symmetrically, as shown in figure 23. They have the additional feature that they are usually smooth in outline and that in a roentgeno-

gram they will usually show a shadow with a sharply demarcated outline.

Fibroma of the esophagus, which occurred in 3 patients who were operated on for its removal, as shown

Fig. 24.—This roentgenogram demonstrates a fibroma of the esophagus as brought out by barium sulfate in the esophagus, showing the intrathoracic location and how readily it can, on palpation, simulate an intrathoracic goiter, particularly when one remembers that it ascends and descends with swallowing.

in figures 24 and 25, is the only tumor of the lower part of the neck other than intrathoracic goiter which ascends and descends with swallowing. Outside of the fact that its outline frequently can be brought out when barium sulfate is ingested, showing distortion of

Fig. 25.—Specimen of the fibroma of the esophagus removed through the neck.

the esophagus, it is practically impossible to distinguish it by roentgenogram or by palpation from an intrathoracic goiter. There is a point which becomes valuable at the time of operative exposure, by means

of which it can be settled that this intrathoracic tumor, occurring on the lower portion of the neck, is an intrathoracic goiter or an intrathoracic fibroma of the esophagus, and that is the relationship of the recurrent laryngeal nerve and the inferior thyroid artery to the tumor. As the neck is opened and the tumor exposed, if the inferior thyroid artery and the recurrent laryngeal nerve run over the anterior surface of the intrathoracic tumor, it will be a tumor of esophageal origin and not of thyroid origin, for if the tumor be of thyroid origin the inferior thyroid artery and the recurrent laryngeal nerve, because of their developmental origin and anatomic course, will be behind the tumor. In all 3 cases of fibroma of the esophagus, the tumors were successfully removed without opening the esophagus and contaminating the mediastinum.

There occasionally arise secondary malignant growths in any location in the neck, such as discrete tumors of Virchow's gland behind the insertion of the left sternomastoid process. This has been such a classic lesion that one should never fail to remember it and to search for it in any examinations of the neck for tumors. Failure to find Virchow's glands and thus demonstrate them as secondary to carcinoma of the stomach has occurred unfortunately more than once in every one's experience and has resulted in an unnecessary exploration to determine the operability in carcinoma of the stomach when, had the gland been discovered, inoperability could have been determined and exploratory operation avoided. Virchow's glands occur as single discrete movable tumors or can have extended until they are represented by a firm fixed mass behind the insertion of the sternomastoid, with a broad fixed base and a firm apex pointing upward. At this stage, secondary extension in the region about the thoracic duct has taken place, and these can rarely be missed.

Another type of secondary malignant growth, secondary to carcinoma particularly in the upper lobe of the lung, will occasionally be observed extending above the clavicle. It is a fixed firm mass, unfortunately at times the first evidence of the presence of such a bronchiogenic carcinoma.

In discussing the diagnosis of tumors of the neck, I am aware of the fact that even after extensive experience with such tumors such discussions seem inadequate and that one can do no more than mention some of the features of these tumors which will make one suspicious of what the diagnosis may prove to be if the tumor is removed and the pathologic report received. So uncertain do I feel, both as to diagnosis and the possibility of malignancy, that in practically all patients with tumors of the neck who come to me for opinion, one of two things is usually done: A gland is removed for pathologic report, or the tumor is explored with the purpose of removing it.

SUMMARY

The importance of immediate removal of tumors of the neck and a pathologic report, because of the danger of malignancy, is stressed.

The various types of tumors of the neck, median, single, lateral, single and multiple, are listed and certain of their features discussed.

The uncertainties in determining the exact nature of all tumors of the neck, exclusive of thyroglossal cysts, adenomas of the thyroid, the neck dermoid and the cystic hygromas, are stressed, and the need for early exploration with the purpose of removal or an early biopsy in multiple tumors is strongly urged.

FUNDAMENTALS IN THE DIAGNOSIS OF JAUNDICE

ALBERT M. SNELL, M.D.
Rochester, Minn.

For more than two decades medical literature has been replete with publications bearing on hepatic physiology in health and disease and on laboratory methods of studying hepatic function. Much of the work has been highly specialized and of interest chiefly to investigators engaged in similar studies. The general practitioner has not found in the reports of such studies as much assistance as he might like in dealing with clinical problems of hepatic and biliary disease. In fact, he might easily be excused for pleading ignorance of the matter and leaving the study of the jaundiced patient to persons and organizations specially equipped to deal with such matters.

For several cogent reasons, however, the practitioner may be required to turn his attention again to the matter of diagnosis in the case of jaundiced persons. During the war years the most extensive epidemic of infectious jaundice on record swept across Europe, the Orient, Africa, the Pacific islands and the North American continent and left in its wake several highly important sequelae. The first obviously is the public health problem which may arise in any community in which the disease appears; the second is an increase in the number of older persons affected by the more serious and even fatal forms of hepatitis, including subacute and chronic forms of atrophy of the liver, and by such chronic lesions as the cholangiolitic or biliary types of cirrhosis. There has been an absolute increase in the various forms of atrophy of the liver observed both in this country and in Europe,² and the mortality rate of the more acute form has been distressingly high. A third problem has to do with the transmission of virus hepatitis by the use of blood, blood products, such as liquid or dried plasma, and even contaminated syringes and needles. This form of hepatitis, often designated as "homologous serum jaundice," has carried a mortality rate many times higher than that of the naturally transmitted disease and has led to a curtailment of the use of plasma in many institutions. The differentiation of these "medical" types of jaundice has become a matter of unusual importance, since surgical intervention in such cases is often attended by hepatic insufficiency and death. Finally, the war years saw the growth and development of radical surgical procedures for the relief of biliary obstruction due to carcinoma of the ampulla of Vater and the pancreas. The results to date have been most encouraging and would be even more gratifying if earlier diagnosis were possible in the patient's home environment. It is in the hope of encouraging earlier and better diagnostic studies on jaundiced patients at the time when they first come to the attention of the family physician that this article is written. The principal thesis to be developed is that it should be possible for any practitioner, by obtaining an accurate history, mak-

From the Division of Medicine, Mayo Clinic.
Read in the interim meeting of the American Medical Association, Cleveland, Jan. 8, 1948.

ing a careful physical examination and performing a few technical procedures which do not tax the capacity of a small laboratory, to arrive at a satisfactory working diagnosis for the jaundiced patient.

The family physician has several advantages over other physicians in dealing with jaundiced patients which should not be disregarded. He knows the patient and his background, and can often evaluate the history of onset and the severity of symptoms better than a stranger. He sees the disease at its onset before it is obscured by complicating factors, and he can follow the development of physical signs and laboratory data with less inconvenience and expense to the patient. He can take comfort in the thought that many diagnoses in cases of jaundice have been made in the past on the basis of purely clinical data and that in the last analysis such clinical data plus sound judgment should always outweigh any combination of laboratory findings.

The first step in diagnosis is a tentative classification of the general type of jaundice present. Many classifications have been advanced, the most recent being that of Ducci.³ He listed three types of jaundice as follows: (1) the prehepatic, which includes the various types of hemolytic jaundice and constitutional hepatic dysfunction; (2) the intrahepatic which includes hepatocellular and hepatocanalicular forms, and (3) the posthepatic type of jaundice which includes the benign and malignant varieties of obstructive jaundice.

The hemolytic varieties of jaundice may be recognized by appropriate studies of the structure of the blood and of the products of breakdown of hemoglobin as well as by the fact that acholuria is an associated phenomenon. Evidence of serious hepatic dysfunction is usually absent. The obstructive types may be identified by the signs and symptoms of interference with biliary flow, such as colic, intermittent or permanent acholia, and by the retention in the blood of biliary constituents other than bile pigment. In obstructive jaundice there seldom is evidence of seriously disturbed metabolic function unless the jaundice is of long duration or complicated by infection of the biliary tract. Patients who have intrahepatic or hepatocellular jaundice do not present, as a rule, any evidence of long-continued interference with the flow of bile into the intestine, and, in contrast to the aforementioned types, they give early and conclusive evidence of disturbances of the metabolic functions of the liver. It is on these general diagnostic premises that a distinction sufficient for therapeutic purposes must be made.

THE HISTORY

Of the greatest importance in dealing with any jaundiced patient is a detailed and accurate chronologic history. The various points which such a history should cover will not be reviewed in detail. Particular attention, however, should be paid to three points: (1) the symptoms which either immediately or remotely preceded the onset of jaundice; (2) possible exposures to virus hepatitis, either epidemic or artificially transmitted, and to hepatotoxic agents and (3) a detailed description of any pain which the patient may have suffered before or since jaundice made its appearance. These may be considered separately.

It is unnecessary to point out that a long history of flatulent indigestion, increasing in severity, suggests the

presence of benign calculous cholecystic or inflammatory disease. It is not so well known that pancreatic cancer may begin with similar poorly defined abdominal symptoms which are often thought to be of functional origin. In fact, depressive symptoms and frank psychoneurosis may precede the onset of jaundice. In addition, there may be unexplained pruritus, loss of weight and diarrhea and, in not a few cases, an otherwise unexplained tendency to phlebothrombosis. Pain in pancreatic neoplasm lacks the clearcut and definite character of biliary colic, but may gradually develop to a disabling level.

The onset of hepatitis of the infectious type is usually abrupt, with nausea, anorexia, vomiting, fever and malaise. There are types which have at the onset symptoms which suggest the development of an infection of the upper respiratory tract; in a few cases, too, there may be fairly severe pain in the upper part of the abdomen. Among older patients, the onset of severe hepatitis may be insidious and jaundice may be the first symptom noted. In cases of acute atrophy of the liver (as was often seen in cases of homologous serum jaundice) the onset may be associated with psychiatric symptoms and organic neurologic signs, singly or in combination. Finally, the incidence of a previous jaundice is of importance; this may be a feature of the history of patients with common duct stone, but it is almost equally significant in the history of portal cirrhosis, as Howard and Watson's⁴ recent report indicates.

An inquiry into an exposure to specific hepatic poisons has always constituted an important part of taking the history of a jaundiced patient. At one time, because of the current prevalence of jaundice due to cinchophen, the first question asked of a jaundiced person was whether he had been taking any remedy for rheumatism; an affirmative answer often helped to establish the diagnosis. Inquiries into the use of other drugs were, and are now, only rarely productive. At the Mayo Clinic we are inclined today to center our inquiries on two major points: (1) the consumption of alcohol and (2) the use of blood or blood products, or even of other parenteral treatment, within two to four months of the onset of jaundice.

The hazard incidental to the transmission of hepatitis by blood and blood products has been recognized only recently, but the homologous serum forms of jaundice are of such a serious nature that this possibility must be considered for every jaundiced patient. It is not generally recognized that from 4 to 5 per cent of patients⁵ who receive pooled plasma will have virus hepatitis within two to four months. The incidence following blood transfusion is, of course, definitely less. Frequently, the incidents which have led to the giving of blood or plasma are practically forgotten by the patient in the anxiety which attends the development of a new group of symptoms. A good example of this fact was encountered recently in the case of a patient who was seen about two weeks after the onset of jaundice, which had been ushered in by pain high in the right side of the abdomen, nausea and vomiting. There was a long antecedent history of digestive complaints and a previous cholecystogram had been regarded as indicative of disease of the gallbladder.

Naturally, under the circumstances, a diagnosis of stone in the common duct seemed likely. A review of the patient's history, however, made it apparent that many of her earlier digestive symptoms were due to constipation and an irritable bowel. It was learned also that about three months previously, hemorrhoidectomy had been done and that blood and plasma had been given at that time because of postoperative bleeding. This information was sufficient to halt the plans for surgical procedures and to initiate a careful study of hepatic function, which quickly established the fact that the patient was suffering from serum hepatitis. She made a satisfactory recovery in about eight weeks. This incident has been repeated many times⁶ with various modifications in the past few years and does not always have so fortunate an outcome.

Little discussion regarding other hepatotoxins is needed. The patient's story in regard to alcohol is rarely to be taken at its face value, and one is inclined to become as skeptical as Mallory,⁷ who recently stated that a man's statements in regard to the quantities of alcohol taken can safely be doubled, those of a woman tripled or quadrupled and those of a teetotaler disregarded. Friends and relatives may supply the information; the patient seldom does.

The severity of abdominal pain is a most difficult matter to interpret and yet is of the greatest importance to diagnosis. Much depends on the character of the patient, his memories of previous illnesses and his individual tendency to exaggerate or minimize symptoms which he may have had. Some persons deal only in superlatives when describing their illnesses, while others have a remarkable capacity for forgetting their troubles entirely. Hence, it is not always easy to prove that the pain which a patient may have had was of a severe or colicky nature. Practically all patients who have stones in the common duct have had severe pain and colic at one time or another, although it may not necessarily be chronologically related to the onset of jaundice. Biliary colic is likely to be, but is by no means necessarily, confined to the right upper quadrant of the abdomen. Wherever it may be situated, however, it usually retains its severity, its intermittent character and its tendency to inhibit respiration, and morphine is required for its relief. Antispasmodics and nitrates may occasionally control the individual attack. The pain of the destructive forms of pancreatitis, on the other hand, is less sharply defined in location but is as severe as that caused by stone in the common duct and of much longer duration. Painful seizures may in fact persist over a period of days, and for them hospitalization and the repeated use of narcotics may be required. The pain of pancreatic carcinoma is rarely so severe, is often worse at night and may be confined chiefly to the back. Morphine is rarely required for its control until relatively late in the course of the disease. At least half of all pancreatic and ductal neoplasms produce little or no pain at any time during the early part of the clinical course.

Too much emphasis cannot be placed on the necessity of a painstaking analysis of the history with special reference to the matters just mentioned. The details should be checked and rechecked and confirmation sought from the family or from other physicians who may have attended the patient.

PHYSICAL EXAMINATION

A special search should be made for four bits of objective evidence in any jaundiced patient: spiders, evidence of cancer elsewhere in the body, the size and consistency of the liver and spleen and a palpable gallbladder.

The vascular spider is almost the trademark of long-standing injury to the parenchyma of the liver. Most of these spider nevi are found in the distribution of the superior vena cava and are often most marked about the head, face and neck. They may vary in size but their pulsating central point and the spidery appearance of the surrounding net of capillaries should serve to identify them. They are rarely associated with obstructive jaundice except in that due to long-standing stricture of the common duct.

Search should be made for tumors elsewhere in the body or a history of tumor in the past. Also metastatic nodes should be the object of a careful search. The old and familiar story of the patient with an artificial eye, or a radical mastectomy scar, a large firm liver and jaundice is still repeated in our wards.

A careful examination of the abdomen with reference to the size and consistency of the liver and spleen is also in order in all cases of jaundice. An extremely large liver usually means syphilis, carcinoma or cirrhosis and is not often found in the presence of obstructive jaundice. The spleen is rarely palpable in cases of metastatic malignant disease of the liver and its presence as a palpable tumor indicates primary hepatic disease. The grossly nodular and stony hard liver is usually carcinomatous; the smooth and symmetrically enlarged liver may be largely fatty.

The last and perhaps the most important feature of the physical examination of the abdomen is an attempt to identify a distended gallbladder. Its presence is proof of obstructive jaundice, usually due to neoplasm in the pancreas or ampulla. The palpation of a distended gallbladder seems to be a lost art and one which certainly should be revived. The time-honored practice of examining the patient while he is in a hot tub and after the administration of a sedative will often prove helpful.

Brief comment may be made here about two other physical findings; the color and texture of the skin and the presence of edema. The golden orange color of the jaundice associated with hepatitis may be contrasted to the blackish or greenish hue of obstructive jaundice. A rough thickened skin with factitial dermatitis and melanosis is almost a specific finding in biliary or cholangiolitic cirrhosis. For the patient acutely ill with recent jaundice, particular attention should be paid to the question of edema. Its presence is not common in obstructive jaundice and points to serious injury to the parenchyma of the liver. Frequently pitting edema of the sacrum, ankles and face precedes the development of hepatic coma in the presence of acute atrophy of the liver. Edema developing after a long period of jaundice is of less significance than that appearing early.

LABORATORY STUDIES WITH PARTICULAR REFERENCE TO TESTS OF HEPATIC FUNCTION

The tests devised and proposed for the study of hepatic function in disease are extremely numerous and new ones are added with great regularity. The multiplicity of these tests indicates clearly that none are uniformly satisfactory. Many are excellent laboratory

7. Mallory, T. B.: in discussion on *Acute Cirrhosis of Liver, Alcoholic Type*, Massachusetts Gen. Hosp. Case 33331, New England J. Med. 237: 233-234 (Aug. 14) 1947.

tools for study of particular groups of cases of cirrhosis or hepatitis, but fall short when applied to the more varied material seen in the surgical wards of general hospitals. Others are useful enough but difficult to employ in practice. A good many are not specific tests for hepatic function at all but merely convenient ways of checking certain physiologic disturbances most frequently produced by disease of the parenchyma. These various tests have become so numerous and are used so widely that one may sympathize with the noted surgical authority who complained that most jaundiced patients are "studied to death."

Before tests are undertaken in the individual case, it is well for the physician to pause long enough to determine what he really wants to know. Actually, he is interested chiefly in determining (1) whether there is evidence of mechanical obstruction to the extrahepatic bile passages and (2) whether there is evidence of injury to the metabolic functions of the liver. Rather simple procedures which can be carried out in most hospitals will give this information. The tests which are considered to form an indispensable minimum are the following: (1) the Harrison spot test or methylene blue test for bilirubin in the urine; (2) duodenal drainage to determine the presence or absence of bile in the duodenum; (3) determination of the icterus index (or serum bilirubin) preferably done on more than one occasion to determine the depth and consistency of jaundice; (4) one or more of the simple flocculation tests, of which that performed with thymol in a barbiturate buffer seems to be about the most reliable and sensitive, and (5) determination of the prothrombin time and its response to the injection of a single dose of vitamin K. If one wishes to go farther with study and if facilities are available, determination of serum cholesterol and cholesterol esters and of alkaline phosphatase is often helpful to check on the presence of biliary constituents other than bilirubin in serum. With the results of these tests, added to the aforementioned clinical data, a reasonably accurate appraisal of the situation may be made.

Some consideration of these individual points would appear to be in order. An icterus index, especially if it is determined on successive days, will indicate the depth of jaundice. If the index is consistently more than 100 (normal is usually 10 or less) the patient most probably has either complete carcinomatous obstruction to the duct or severe necrotic hepatitis. With levels of less than 100 either calculous obstruction or a milder and more chronic type of hepatitis is most probably present. A fluctuating icterus index indicates a stone in the common duct; a high constant level, complete neoplastic obstruction; and a gradually falling level, subsiding hepatitis. The icterus index is, of course, a simple colorimetric comparison of the serum with a bichromate standard and does not distinguish pigments such as carotene, which may discolor the serum, from bilirubin. For this reason, actual determinations of the quantity of bilirubin in the blood in both its direct-reacting and indirect-reacting forms are desirable if suitable laboratory facilities are available. If not, a fairly good idea of the depth of serum bilirubin can be had by remembering that an icterus index of 100 represents a bilirubin level of 10 to 12 mg. per hundred cubic centimeters.

When the icterus index is 50 or less, the prehepatic (acholuric) forms of jaundice previously mentioned may be excluded easily by a test of the urine for

urobilin. A simple test of this kind performed on the urine also will give evidence of infectious or serum hepatitis in the preicteric stage and not infrequently will indicate small increases in the serum bilirubin occasioned by a stone in the common duct.

With greater degrees of jaundice and especially if the icterus index exceeds 100, it becomes necessary to determine the patency of the bile passages. The most constant single sign of neoplastic obstruction to the bile passages is complete exclusion of bile from the duodenum.⁸ The use of duodenal drainage is recommended for this purpose chiefly because it is within the reach of every one and, if the position of the tip of the tube is checked roentgenoscopically, study of drainage material has proved reasonably accurate. In doubtful cases, the procedure should be repeated. The presence of gross blood in the drainage is almost pathognomonic of neoplasm, especially if no bile is obtained at the same drainage. The presence of bile, even in rather small quantities, is sufficient proof that the ducts are not completely obstructed. The importance of locating the tip of the tube by roentgenoscopic observation cannot be overestimated, especially in the presence of acholia.

My colleagues and I have little confidence in the visual examination of the stools and have found that the widely used Schmidt test for bile in the stools is scarcely more reliable. If laboratory facilities are available and there is an opportunity to make accurate collections of urine and feces for periods of two to four days, studies of fecal and urinary urobilinogen are invaluable. Such studies are, however, of little value unless they are done meticulously. The significance of the presence or absence of urobilinogen in casually voided specimens of urine cannot be depended on in the absence of confirmatory evidence.

Space does not permit a discussion of the theoretical basis of the various flocculation tests. They are, of course, not specific tests of hepatic function, but measure certain phenomena associated with changes in plasma proteins. For this reason they may give positive results in the absence of hepatic disease. The well known cephalin-cholesterol flocculation test probably depends on the lack of an inhibiting substance associated with normal levels of serum albumin and the presence of an accelerating substance which parallels a rise in serum globulin. The thymol turbidity test appears to depend on a lipid complex, associated with beta globulin, plus a rise in gamma globulin.⁹ The turbidimetric test recently described by Kunkel¹⁰ depends on increases in gamma globulin alone. The first mentioned procedure, the cephalin-cholesterol flocculation has, unfortunately, a considerable margin of error in that it often gives a positive result in obstructive jaundice. Turbidimetric determinations of gamma globulin have not been employed widely enough to justify a final statement as to their usefulness, but a small experience indicates that the test probably gives normal values in obstructive jaundice. The thymol turbidity test as a rule has given consistently negative results in the presence of obstructive jaundice except in a few cases of stricture of the common duct of

long standing. Unfortunately, the test may give negative or only weakly positive results in cirrhosis, especially in that of alcoholic origin, and at certain stages in the course of toxic hepatitis. A strongly positive result is to be expected in late infectious or serum hepatitis, especially of the more severe degrees, and in the various forms of acute and subacute atrophy of the liver. When practicable, all flocculation tests should be checked against the level of serum albumin and globulin, although this statement does not imply any necessary parallelism in the results of the two determinations.

The determination of blood prothrombin is an essential part in the study of every jaundiced patient and may be quickly and easily done by one of several simplified bedside methods. If the prothrombin time is within normal limits, it gives no information of diagnostic value, but, if the time is elevated, a ready method of distinguishing obstructive from parenchymatous jaundice can be used. This consists of an intravenous dose of one of the various substitutes of vitamin K and repetition of the test for prothrombin in two to four hours. A marked reduction in prothrombin time is the rule in biliary obstruction, whereas in primary hepatic injury, little or no response is noted.¹¹

The serum concentration of alkaline phosphatase, a substance which is widely distributed in the body and usually excreted in part in the bile, is elevated in obstructive jaundice and is either normal or reduced in primary hepatic injury. MacLagan¹² has commented on the fact that the determination of phosphatase used in connection with his thymol turbidity test will differentiate obstructive from nonobstructive jaundice in about 80 per cent of cases. The values for cholesterol and cholesterol esters run roughly parallel with those for alkaline phosphatase. The cholesterol esters are characteristically reduced in cases of atrophy of the liver, a fact which may have considerable prognostic significance.

It is assumed, of course, that findings on routine urinalysis, test for hemoglobin, leukocyte count, flocculation test for syphilis and a roentgenogram are available. Certain accessory laboratory studies are also exceedingly helpful in the study of jaundiced patients. In any doubtful case of jaundice, an examination of the blood with special reference to the structure of the cells as seen in stained smears may pay important dividends. Even a rather cursory examination will reveal the presence of sickle cell anemia or leukemia, the spherical microcyte of congenital hemolytic icterus or the macrocytic anemia of primary hepatic disease. Since hemolytic jaundice is associated with gallstones in about 60 per cent of cases, and since the other laboratory findings referable to jaundice may be somewhat altered in the presence of stone in the duct, the blood smear remains the best single aid to diagnosis of hemolytic jaundice when stones are also present.

The roentgenologic examination of the gallbladder after the administration of dye has relatively little to offer the jaundiced patient. One may occasionally see stones or a primary shadow, but the usual cholecystographic technic does not permit satisfactory visuali-

zation of the gallbladder in the presence of occluded bile passages or hepatic damage. A simple roentgenogram of the upper part of the abdomen may reveal pancreatic or biliary calculi; such roentgenograms should always be taken when patients describe severe or recurrent pain with posterior extension. Roentgenograms of the esophagus, stomach and duodenum may be helpful in excluding primary malignant lesions in these organs. They also may bring out two other important bits of evidence: (1) varicosities in the esophagus, which are of themselves practically sufficient to prove the presence of cirrhosis of long standing and (2) widening and distortion of the duodenal loop which may point to a new growth in the head of the pancreas.

SOME DIAGNOSTIC POINTS IN VARIOUS SYNDROMES ASSOCIATED WITH JAUNDICE

Infectious Hepatitis.—Most physicians who were in military service have had long and unhappy experience with infectious hepatitis, and not a few have suffered from it personally. It requires little comment here except to note the frequency and relative severity of late relapses. These may be of long duration and seem to be more persistent and severe among older persons. The diagnosis should not be abandoned simply because jaundice recurs or is slow in clearing. Persistently positive results of the thymol turbidity test are clinically useful and reliable in such circumstances.

Homologous Serum Jaundice.—Homologous serum jaundice may be detected in its preicteric phase by various tests of hepatic function of which the sulfobromophthalein sodium and cephalin-cholesterol flocculation tests are the most reliable. Jaundice may develop suddenly and the disease may run a rapidly fatal course. However, in other fatal cases the course may be protracted. There may be increases or decreases in the depth of jaundice, anemia, gross hepatic enlargement with ascites, hemorrhage, pruritus and abdominal pain.¹³ It is in such cases that the irregular course, pain and fever suggest the possible presence of stone in the biliary tract, and, in fact, stones may appear as a terminal event. Their removal when subacute atrophy of the liver is associated has done little to benefit the patient or alter the course of the disease.

Cholangiolitic Cirrhosis.—Cholangiolitic cirrhosis has attracted much attention lately because of the possibility that it is a late residue of virus hepatitis. It is recognized clinically by its chronic course, melanosis, factitial dermatitis, the presence of a large liver and spleen, the remarkable preservation of the metabolic functions of the liver and the persistent elevated levels of bilirubin, phosphatase and cholesterol in the serum. It is not known to be amenable to either medical or surgical treatment.

Stone in the Common Duct.—One may paraphrase the old aphorism regarding syphilis and say that, if one knew stone in the common duct in all its clinical manifestations, all other knowledge of biliary and hepatic disease would be at one's disposal. For clinical purposes, it must be recalled that practically any syndrome associated with intrabiliary or extrabiliary disease can be closely mimicked by stone. Endless examples could be cited to prove this point. This fact also must be considered in diagnosis and the selection of cases for surgical exploration. Two points may be

11. Lord, J. W., Jr., and Andrus, W. DeW.: Differentiation of Intrahepatic and Extrahepatic Jaundice: Response of the Plasma Prothrombin to Intramuscular Injection of Menadione (2 Methyl-1, 4-Naphthoquinone) as Diagnostic Aid, *Arch. Int. Med.* **68**: 199-210 (Aug.) 1941.

13. Lucke, B.: The Pathology of Fatal Epidemic Hepatitis, *Am. J. Path.* **20**: 471-493 (May) 1944.

helpful in this connection: (1) it is rare for a patient with common duct stone not to have had colic at some time and (2) it is rare for a stone to cause complete obstruction of the ducts for any length of time.

Strictures.—Postoperative strictures of the biliary ducts are on the increase and as always present a grave problem for the surgeon. Diagnosis, however, is easy if the examining physician inquires carefully into the postoperative course of the patient. A story of intermittent jaundice with biliary fistula which alternately opened and closed is almost diagnostic. In late cases splenomegaly and vascular spiders are not uncommon, pruritus is severe, and latent hemorrhagic tendencies are often detected. Laboratory studies often indicate evidence of injury to the parenchyma of the liver, which is not ordinarily of a degree to interfere with successful surgical results.

Chronic Destructive Pancreatitis With or Without Stones.—Chronic destructive pancreatitis with or without stones is commoner than is generally believed. It may be recognized by the persistence and severity of its painful seizures, by the fact that it may be associated with steatorrhea, fatty liver and diabetes mellitus and by the evidence of regurgitation of pancreatic enzymes, lipase and amylase, into the blood stream. It is a dramatic and violent disease, unlike the insidious pancreatic carcinoma. It rarely produces complete biliary obstruction and may pass through numerous episodes without demonstrable icterus.

INDICATIONS AND CONTRAINDICATIONS TO SURGICAL TREATMENT

It may be inferred from this brief résumé that a good history, a painstaking physical examination and certain minimal laboratory studies will point the way to an accurate diagnosis of jaundice in a large majority of cases. Unfortunately, however, there are many persons whose histories are confusing, whose physical findings are meager and on whom laboratory studies give equivocal results. In such persons, a reasonable doubt in regard to the nature of the diagnosis must remain. It is of such patients that one may say, as did one famous surgical authority, that a guess is a poor peg on which to hang a man's life and that the possible benefits of exploration may well justify the risk. This widely quoted dictum has been responsible for many rather unfortunate surgical procedures on jaundiced patients, many of which might have been avoided by reference to the statistical odds in the individual case.

There are four well recognized indications for explorations in the presence of jaundice: (1) a reliable history of gallstones, colic or preferably both; (2) proved intermittent biliary obstruction with fever; (3) a patent biliary fistula, and (4) proved complete and permanent biliary obstruction. The reader is invited to note the words "reliable" and "proved." The principal problem is to be sure of the facts; if any doubt exists, the data should be reviewed and checked.

Only a few of the many contraindications to surgical procedures on jaundiced patients will be mentioned. All are directed at the avoidance of surgical procedures on patients with jaundice caused by injury to the parenchyma of the liver alone. Perhaps the most important is the history of transfusion of blood or plasma infusions from two to four months prior to the onset of jaundice. In these circumstances, the

patient's interests are best served by deferring a decision until further observation confirms or disproves the diagnosis of homologous serum jaundice. A second important contraindication is the presence of vascular spiders, edema and evidence of collateral circulation, singly or in combination. These contraindications may be waived in the presence of a known postoperative stricture of the common duct, but hardly otherwise. A third contraindication is the persistence of intense jaundice (icterus indexes of 100 or more) in the presence of patent bile passages. Such patients are almost invariably suffering from primary hepatic injury and will not be helped by operation. A final, and by no means the least important, contraindication is a prolonged prothrombin time which does not respond to the administration of vitamin K. If the indications and contraindications stated are borne in mind, less and less should be heard of explorations done on patients with primary liver disease; surgical results should improve and the mortality rate decrease.

Special Article

CARCINOMA OF THE BREAST

C. D. HAAGENSEN, M.D.
New York

(Concluded from page 205)

This article is the fifteenth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment.

PROVING THE DIAGNOSIS

The last generation of surgeons had to rely solely on their knowledge of gross pathology in proving the nature of tumors of the breast, and this often led them astray. Thus Bloodgood,³ writing in 1914 of his experience in Halsted's clinic in the diagnosis of breast tumors, stated: "Among 542 benign lesions . . . 54, or 10 per cent, have been incorrectly treated for cancer [i. e., radical mastectomy was done]. . . . It is interesting to note that among these 54 benign lesions which were treated as malignant, in 27 cases the diagnosis of malignancy was based upon the clinical appearance alone. . . . In 24 cases, the diagnosis of cancer was based upon the gross appearance at exploratory incision. . . ."

Fortunately, this kind of mistake is no longer necessary, for today there are quick and sure methods of proving the diagnosis microscopically. Pathology has grown up and become a senior, partner of surgery in dealing with lesions of the breast. The skilled pathologist is just as essential as the surgeon, and I believe that the treatment of tumors of the breast should not be attempted in communities that are unwilling or unable to support a properly trained pathologist.

Biopsy.—We are all agreed today that biopsy and immediate microscopic examination are often indicated. The only differences of opinion are in regard to the method.

Aspiration Biopsy: Aspiration biopsy has been advocated by the Memorial Hospital group for some years and has gained many adherents. The procedure is ordi-

3. Bloodgood, J. C.: Diagnosis and Treatment of Borderline Pathological Lesions, Surg., Gynec. & Obst., 18: 9, 1914.

narly carried out in the surgeon's office, before the patient has entered the hospital. With the patient under local anesthesia a large bore needle attached to a syringe is inserted into the tumor and, while suction is exerted, is withdrawn and advanced several times, sucking up a core of tumor cells into the bore of the needle.

Fig. 34.—A cyst of the breast masking a carcinoma.

The material thus obtained is smeared on a glass slide and fixed and stained. In this manner a fairly accurate impression of the cell types of the tumor is gained, although the details of cell structure are somewhat distorted by the crudity of the fixation and staining.

This kind of preparation gives no information, however, as to the cellular arrangement and the general architecture of the lesion. The pathologist is forced to rely in making his diagnosis on cytology rather than on histology. This is a great handicap. For example, in distinguishing certain better differentiated types of carcinoma of the breast from benign epithelial proliferation, the arrangement of the cells within the ducts, as well as their invasive character, is just as important as the type of cells—and aspiration biopsy does not provide this crucial information. This is the main reason why Dr Stout and I, working together at this problem over a period of years, have come to believe that aspiration biopsy is not a reliable method of diagnosing lesions in the breast.

There is also a theoretic objection to aspiration biopsy on the ground of its roughness. A good deal of force is required to plunge a large bore needle into the firm structure of mammary carcinoma—and this is exerted not once but several times. We fear that this trauma may squeeze carcinoma emboli into veins. If our emphasis on gentleness in manipulating carcinoma of the breast means anything we should avoid a method as rough as aspiration biopsy.

Another disadvantage of aspiration biopsy is that cystic disease and carcinoma may coexist in the breast, the cyst or cysts being prominent and the carcinoma small, as in figure 34. Aspiration would empty the cyst but leave the inconspicuous carcinoma undetected. Surgical exploration of a case of this kind, with excision of the cyst and careful inspection and palpation of the surrounding breast tissue through the open wound, would be more likely to detect the carcinoma.

A final objection to aspiration biopsy is that success with this method becomes more and more difficult as

the carcinoma diminishes in size. It is difficult indeed to hit with the point of the aspirating needle a nodule in the depths of the breast measuring only 4 or 5 mm. in diameter. Yet, as the education of women in the detection of tumors of the breast improves, lesions of this size are seen more and more frequently. Figure 35 shows such a primary carcinoma measuring 4 mm. in diameter which we recently excised for biopsy. It is just in such difficult diagnoses, when one must have a reliable method of proving the nature of the tumor, that the aspiration method will most often fail.

Incisional Biopsy: These are some of the reasons why we prefer incisional biopsy and frozen section as the method of choice in proving the nature of tumors of the breast. Our procedure is as follows: The diagnostic problem is discussed fully with the patient, as gently and as hopefully as possible. Her consent for radical mastectomy, should it be required, is obtained. She is admitted to the hospital and all preparations made for the radical operation. The surgical pathologist often sees and examines the patient before operation. He is regularly present in the operating room when the biopsy is done. "Pentothal sodium" administered intravenously and supplemented with nitrous oxide and oxygen is our anesthetic of choice. We do not use local anesthesia: it puts the patient on the rack of suspense while the diagnosis is being made.

A small incision, 3 or 4 cm. in length, is made through the skin over the tumor, and deepened to expose its surface. All vessels are meticulously caught with mosquito clamps and tied with fine silk, so that the wound is perfectly dry and the surgeon is able to see the cut surface of the lesion as he incises it. If the tumor is solid a small wedge, measuring about 3 by 5 mm., is excised. This is ordinarily adequate for our frozen section. On infrequent occasions when the microscopic diagnosis is difficult the pathologist may ask for a second small wedge of tissue. We do not excise the whole tumor for diagnosis unless it is a very small one, measuring only a few millimeters in diameter, for we believe that the practice adds unnecessarily to the risk

Fig. 35.—A very small carcinoma of the breast measuring 4 mm. in diameter.

of producing metastasis. If the carcinoma is of some size the line of local excision will cut across dilated veins which may carry off carcinoma emboli. Biopsy must, of course, always carry with it some degree of risk of causing metastases. Since we cannot avoid it in many cases our aim is at least to minimize the risk.

The argument that excising the whole tumor for biopsy is safer because the line of excision is around

and not through the tumor does not, of course, have the approval of the pathologist. He knows that carcinoma frequently infiltrates far beyond the grossly visible limits of the disease and that no surgeon can be reasonably sure that a local excision will get beyond it.

The small wedge which we excise for frozen section is heated for a few seconds in Bouin's fixative. Prolonged heating is not desirable, for it distorts the tissue too much. It is then frozen and cut on a freezing microtome. We cut a block of tissue of sufficient size to show the architecture of the tumor. We do not depend on a section so small that only a few cells are shown. The sections are floated out in a basin of water and picked out on a glass rod and stained in an aqueous polychrome stain. Five or ten minutes only are required to prepare these sections.

Although we believe that frozen sections made in this manner provide the best immediately available microscopic evidence, we have learned that there is one type of neoplasm in the breast in which nothing except a good paraffin section suffices. This is the papillary growth situated at a distance from the subareolar area of the breast. It is so difficult to distinguish papillary carcinoma from papilloma in this location that preliminary biopsy as a separate operative procedure, and careful study of paraffin sections, should precede any operative therapy.

There are rare occasions when the frozen section technic will fail to give an immediate diagnosis because the microscopic picture is confused by the presence of inflammation or by the variety and richness of the epithelial proliferation. The best differentiated carcinomas, of course, give the most difficulty. On these rare occasions when the pathologist cannot be certain what the lesion is the surgeon closes the wound and waits for a paraffin section, available in twenty-four hours. *He does not proceed with mastectomy without being certain of his diagnosis.*

The surgeon who performs a radical mastectomy merely on the suspicion that he is dealing with a carcinoma, because he feels that it is the best thing to do in this dilemma, runs an unnecessary risk of mutilating the patient needlessly. A study of a series of cases of carcinoma of the breast in our clinic in which there was a delay of from one to ten days between biopsy and the radical mastectomy showed that the end results were no worse than in cases in which immediate operations were carried out. While we do not of course recommend delaying operation when it can be done at once, this evidence justifies delay which is unavoidable, as for instance when the frozen sections do not yield a definite diagnosis or when a pathologist is not available to prepare frozen sections and the surgeon has no other course but to excise tissue for biopsy and send it to a pathologist in the community for a twenty-four hour paraffin section.

Simple mastectomy as an alternative procedure when the biopsy fails to yield an immediate microscopic diagnosis is, in our opinion, equally unwise. If the lesion finally proves to be benign, removal of the breast is unnecessary. If it proves to be a carcinoma a simple mastectomy spoils the field, speaking in a technical sense, for a proper radical mastectomy, besides putting the patient through an additional major operation.

To return to the surgeon in the operating room who has just received word from the pathologist that the frozen section shows carcinoma, I recommend that he place a small piece of gauze soaked in formaldehyde in the wound or coagulate it with the electrocautery, and

close it tightly with a continuous suture of silk. Since the danger of blood oozing from the biopsy wound and carrying cancer cells into the operative field of the subsequent radical mastectomy is very real, it has been our custom to seal the wound with a patch of rubber dam cemented in place with rubber cement.

This method of proving the diagnosis of a tumor of the breast is not only the most reliable one with which we are familiar, but it is the one most likely to lead to prompt treatment. When it has been explained to the patient it leaves her in no doubt about the serious possibilities of her seemingly innocuous tumor of the breast. She is usually willing to come into the hospital at once. From the physician's point of view it provides him with a direct and adequate plan to follow for every patient with a lesion in the breast. He will not be tempted to make a biopsy of the tumor in his office. If he is not a member of the surgical staff of a reputable hospital or is not himself qualified to perform a radical mastectomy, he will refer the patient immediately to a surgeon who is properly qualified. He will not procrastinate because he is in doubt about the nature of the lesion, sending the patient away with instructions to apply heat or cold, or reassuring her and telling her to return in a month. He will instead send at once every woman with a dominant tumor in her breast, or retraction signs, or abnormal erosion or discharge from the nipple, into the hospital to have the nature of her lesion proved by biopsy. The practice of this simple rule is the best hope of reducing the mortality of carcinoma of the breast today.

TREATMENT OF CARCINOMA OF THE BREAST

The diagnosis of carcinoma having been proved, the surgeon must decide how to treat it. This decision is a complex and technical one, but it should concern the general practitioner or internist who makes the original clinical diagnosis at least to the extent that he should have an understanding of the basic principles of the modern therapeutic attack on cancer of the breast. He must know enough to assure himself that his patient is getting the best possible treatment.

First of all, of course, he must have seen enough of the results of the modern radical surgical attack on cancer of the breast to believe that the disease can be cured. I assume that the reason why some physicians are content to do half-hearted and incomplete operations for cancer of the breast is simply that in their personal experience, with the surgical methods they have seen tried, the disease has been invariably fatal. Our system of medical education is not yet well enough developed in this country to make it possible for every medical student, or even every hospital intern, to have seen in the follow-up clinic patients cured of carcinoma of the breast by radical surgery. Until this kind of evidence is supplied to students they will not be convinced, for they share the prejudice that lies deep in the heart of every man that cancer is incurable. The truth is that, considering all patients who come for treatment of carcinoma of the breast, including those whose disease is the most advanced, five year clinical cure can be achieved today in about one third. By this I mean that the patient remains free of all evidence of her carcinoma for five years. If the patients with far advanced and inoperable lesions are excluded from the calculation, about one half of those operated on remain well for at least five years. In patients without axillary metastases the five year cure rate reaches 70 per cent.

After five years have elapsed the frequency of recurrence is much less, as shown in Simmons' ⁴ chart (fig. 36) of the late results of operation. In his series of cases these late recurrences developed only in patients who had axillary metastases at the time of operation. One can therefore say that a woman whose disease is attacked before axillary metastases have developed has a 70 per cent chance not only of five year cure but of permanent cure.

If one could convince all practicing physicians of this truth one should have gone a long way toward improving present day treatment of carcinoma of the breast.

When methods of treatment are discussed it is fundamental to make a distinction between cure and palliation. This is an important distinction because, as I shall show later, attempts to cure lesions which are quite beyond the reach of present methods not only discredit the methods but actually increase the patient's discomfort and shorten her life.

There are only two methods of treatment which can be claimed to cure carcinoma of the breast—radiation and surgery. There is today such a wide range of opinion concerning the merits of radiation that its use must be considered in some detail.

Fig. 36. Ten year end results in cancer of breast. Solid line, total, 134 cases, 33 per cent cures. Line of dots, axilla involved, 95 cases, 18 per cent cures. Line of dashes, axilla not involved, 39 cases, 70 per cent cures. (Patients living with disease at end of ten years are counted as dead.)

ROLE OF RADIATION

Radium, applied interstitially in needles, has been used extensively for carcinoma of the breast by Mr. Geoffrey Keynes ⁵ at Saint Bartholomew's Hospital. In this country McKittrick ⁶ has given the method a thorough trial and has found it less desirable than surgery in operable cases. Pain and limitation of arm motion are disturbing late after-effects of the radium treatment. A more important disadvantage is the fact that the method cannot be depended on to destroy carcinoma in the axillary nodes. This truth is apparent in the report of Mr. J. P. Ross, ⁷ from Keynes's own clinic, concerning the microscopic observations in a series of cases in which the breast and some of the axillary lymph nodes were removed surgically three months after the completion of the radium treatment. In 30 per cent of the cases active-looking carcinoma cells were found in the axillary lymph nodes. Surgical treatment, on the other hand, is highly efficient in eradicating carcinoma in the axilla. Local recurrence develops in the axilla in less than 5 per cent of the cases in which

a thoroughly radical operation is carried out. In view of this fact it would seem to me that interstitial radium has no proper place in the treatment of operable mammary carcinoma.

Roentgen radiation deserves more serious consideration as a curative method, although I must admit that in our own clinic at the Presbyterian Hospital our experience with it as a curative agent has been discouraging. We have reluctantly come to the conclusion that roentgen rays do not permanently eradicate carcinoma in the breast, although if given in maximum doses they often lock the disease up in scar tissue for several years.

This conclusion has been forced on us from our experience with an experimental series of 38 cases in which treatment was given between 1933 and 1937 at the Presbyterian Hospital. In this series large doses of roentgen rays were given, and radical mastectomy

Fig. 37. —Pretreatment biopsy of carcinoma of the breast.

then performed. The roentgen treatment in these cases has been described by Lenz, ⁸ who supervised it. The fractional dose method was used, 100 r to 200 r being given daily to each of one or more portals, depending on the patient's tolerance. The breast was treated through four portals directed tangentially to the chest wall, and often through an additional portal directly over the tumor. The axilla and supraclavicular regions were treated through an anterior and a posterior portal and through a third direct axillary portal. Approximately 2,000 r in air was given to each of the breast and axillary portals. The tumor dose to the primary lesion in the breast reached 4,500 r.

Approximately two months are required for this type of radiation, and it is necessary to wait at least another month for the severe cutaneous reaction to subside before it is safe to carry out a thoroughly radical

mastectomy. The tissues removed at operation were studied by Stout with special attention to the question of the destructive effects of radiation. Many blocks of tissue were studied from each specimen. In every case in the series persisting carcinoma cells were found, although the destructive effect of the radiation was often

Fig. 38.—Carcinoma of the breast (same case as in fig. 37) after treatment with 8,500 r.

great. The details of the histologic findings in representative cases in this series were reported by Beach.⁹ I include photomicrographs from one of these cases. Figure 37 shows the appearance of the primary breast carcinoma in the preradiation biopsy. Figure 38 shows the same tumor as it appeared when the breast was removed two months after the completion of the roentgen treatment. Only scattered strands of carcinoma cells remained, locked up in a dense hyalinized stroma. Some of these cells appeared to be well preserved although they did not show mitoses, but in most of them the radiation effect was apparent from their gigantic and pyknotic nuclei and vacuolated cytoplasm.

Figure 39 shows the appearance of the axillary lymph node metastases. They appear to be unaffected by the irradiation although they were heavily treated.

The greater resistance to radiation of metastases in lymph nodes is, of course, a well known phenomenon, which is observed in other types of carcinoma. In mammary carcinoma this inability of roentgen treatment to control the axillary metastases is an unsurmountable objection to reliance on this method for cure.

Our objection to reliance on roentgen treatment for the cure of carcinoma of the breast and its axillary metastases is not based on microscopic evidence alone; clinical experience has been equally decisive. We have repeatedly seen patients with operable carcinoma of

the breast in whom intensive roentgen treatment, given in preference to surgery and with the hope of cure, caused only temporary regression of the disease. After an interval, sometimes lasting as long as five years, the disease broke out of its fibrous bonds and reappeared locally. The following case history is a typical one.

In September 1938, H. M., a woman aged 36, discovered a small tumor in the upper outer sector of her left breast. There was a single small clinically involved axillary node. The tumor of the breast was excised for biopsy at another hospital and proved to be a carcinoma. The patient refused radical mastectomy and was therefore treated intensively with roentgen rays. The breast received a total of 9,750 r in air through five different portals, given in two separate series of treatments over a period of fifteen months. The axilla received a total of 8,650 r in air given through three portals during the same period.

Both the tumor of the breast and the axillary node disappeared after the radiation. Some thickening in the region of the original tumor was noted in December 1942. This induration increased slowly. By March 1944, it had grown so that the radiologist in charge of the patient became convinced that it represented a local recurrence. Being unable to give further radiation he persuaded the patient to have an operation. She entered the Presbyterian Hospital April 5, 1944, five and one-half years after radiation had been started.

The skin over the axilla and upper outer portion of the breast showed pronounced telangiectasia and atrophy. Beneath the center of the radiated area in the breast there was a firm mass 4 cm. in diameter, fixed to the pectoral fascia. No axillary or

Fig. 39.—Axillary metastases (same case as in figs. 37 and 38) after treatment with 4,500 r.

supraclavicular nodes were palpated. Roentgen studies failed to show metastases in lungs or bones. Radical mastectomy was therefore done on April 7, 1944, a large Thiersch graft being used to cover the operative defect on the chest wall. Microscopic study showed well preserved carcinoma in the breast and a small metastasis in one axillary lymph node. To date (October 1947) there has been no local recurrence or evidence of distant metastases.

9. Beach, A.: The Effects of Roentgen-Ray Dosage in Breast Carcinoma, *Am. J. Roentgenol.* **46**: 89, 1941.

The use of roentgen rays prophylactically as a supplement to surgery is another question—one much debated today. Prophylactic radiation has been given either before or after operation, the latter form being the more popular one. Three portals have usually been used—a supraclavicular portal, one which includes the operative field on the chest wall, and a third directed to the axilla. The total dosage and the rate at which it has been given have varied widely. At the Congress of the German Roentgen Ray Society in 1926, for instance, a dose of 300 r at bimonthly intervals for as long as two years postoperatively was recommended, and this type of protracted therapy was much used everywhere during the following decade. During recent years most radiotherapists have concentrated their treatment and raised their dosage of prophylactic radiation somewhat. A typical plan of treatment today would administer a total of 1,000 r to each of the three portals mentioned, given at the rate of 250 r to one or more portals twice weekly. Some radiotherapists push the total dosage to each portal up as high as 2,000 r, but this is unusual.

It is at once apparent that these prophylactic doses of radiation are very small indeed as compared with the doses given by Lenz in our Presbyterian Hospital experimental series of cases in which preoperative treatment was given: They amount at most only to about one quarter of the total dosage in our series. Moreover, the method which Lenz used of administering radiation in small daily doses is a more effective one than the old fashioned technic of giving larger single doses repeated at long intervals.

In view of the fact that carcinoma was not entirely destroyed by the large doses used in our experimental series it seems unlikely that the small amounts of radiation commonly given prophylactically before or after operation can destroy all carcinoma cells which may have been left in the operative field. It is conceivable that such prophylactic radiation may restrain the growth of residual disease to some extent and delay its reappearance, but it is unlikely that such restraint will alter the late results much.

This theoretic ineffectiveness of prophylactic radiation is substantiated by study of the actual results. Many reports have of course been published in which it was claimed that prophylactic radiation significantly raised the cure rate, but most of this evidence can be viewed with suspicion because the series of cases reported are not strictly comparable. It must be realized that we have been going through an era in which the results of the exclusively surgical treatment of breast cancer are steadily improving. I will refer again to this fact later in my discussion. For this reason it is not proper to compare recent case series in which surgery has been supplemented by irradiation, with earlier case series in which surgery alone was used. Ahlborn's¹⁰ paper and Marshall and Hare's¹¹ recent report are good examples of this kind of improper comparison.

Carefully compiled case series comparing the results of operation with those of operation supplemented by radiation have been reported by Simmons, Taylor and Wallace¹² from the Massachusetts General Hospital

and by Harrington¹³ from the Mayo Clinic. The former reported that prophylactic radiation did not influence the results of operation. The latter found a slight increase in the percentage of five year survivors in the radiated group, but concluded that irradiation had not had a great effect on the late results of surgical treatment.

Even if one admits that prophylactic radiation may have some restraining effect on carcinoma cells left in the operative field, its use routinely in all patients seems a heavy price for a small possible gain. It has been shown by Taylor and his associates at the Massachusetts General Hospital, as well as in our own clinic, that if patients are properly selected for operation and a thorough operation is done, only about 10 per cent have local recurrence in the field of operation, that is, the chest wall and axilla. Prophylactic radiation to these areas can be of benefit therefore only in this 10 per cent, and it has been our experience that when local recurrences do appear in this small group of cases they can be adequately dealt with by radiation given at the time of appearance. These patients do not succumb to their local recurrences. They die from distant metastases—the *bête noire* in cancer of the breast.

These are the considerations which have led us to abandon prophylactic radiation in our own clinic after using it over a period of years. In our experience it was expensive to the patient both economically and biologically. We found no definite evidence that it raised the rate of cure.

There is, however, one type of case in which we continue to give postoperative radiation, but only to the supraclavicular region. It is the type of case in which the surgeon, while performing radical mastectomy on a patient whose disease had appeared to be operable, finds to his chagrin that the axilla contains many small involved nodes extending all the way up to the apex of the axilla. This type of extensive axillary involvement cannot be detected preoperatively by any method with which we are familiar, and the surgeon is thus blindly led into the error of operating on incurable disease, for these patients almost invariably succumb to distant metastases. Surgery does remarkably well in this type of disease on the chest wall, and in the

axilla if it is extensively involved. But since we do not attempt to remove the supraclavicular lymph nodes, which are the next way station for metastases; and which are often involved in these patients with extensive axillary metastases, it seems wise to radiate the supraclavicular area. Lenz gives these patients 3,000 to 4,000 r administered in daily doses of 100 to 200 r.

The question might be raised of the advisability of giving routine prophylactic radiation to the supraclavicular area in the operable group of cases. Our answer would again be that it would not seem worth while to radiate all of these patients when only the few who are doomed to have supraclavicular metastases develop can benefit from the treatment. In our Presbyterian Hospital series of cases of radical mastectomy only 11 per cent of the patients in the operable group of cases subsequently had supraclavicular metastases. Again, it has been our experience that radiation given to these metastases at the time of their appearance holds them in check until more distant metastases in bone or lungs get beyond control. More-

over, radiation to the supraclavicular and axillary areas often increases shoulder discomfort and edema of the arm. We do not wish to inflict this penalty on all our patients for a questionable benefit to a few.

In summary, it can be said that critical evaluation of the evidence at hand does not give radiation any substantial place in the curative attack on carcinoma of the breast. Although it is widely used as a supplement to surgery its value has not been proved.

ROLE OF SURGERY

Surgery remains our sole reliance for the cure of cancer of the breast. With this fact before us our first duty is to try in every way that we can to improve our surgery. The first step in this direction, it has seemed to us, is to select our cases for operation more critically. At the Presbyterian Hospital Dr. Stout and I set out, some years ago, to try to define, from the records of the hospital, in just what types of cases cure can be effected by operation. We were favored in this undertaking by the fact that the unit case records of patients with carcinoma of the breast in the Presbyterian Hospital have been exceptionally complete. They have often included photographs of the lesion, and the clinical descriptions of the lesion have usually been fairly detailed. We analyzed the records of all female patients with carcinoma of the breast coming to the hospital between the years 1915 to 1934, inclusive.

In studying this material we utilized the punch card method. In this way it is not only possible to work out correlations between any number of different factors with ease, but the findings can be checked and counter-checked in a way that is scarcely possible by hand sorting and arithmetic.

Having the punch cards with all the clinical data recorded on them, we were able to study correlations between the local recurrence rate, the five year cure rate and a whole series of clinical features of carcinoma of the breast as recorded in our series of cases.¹⁴ We presented tables showing these correlations for twenty-one different clinical factors. There is not space here to do more than summarize our positive findings.

There were eight types of cases that together formed a group in which surgery did not achieve a single permanent cure (table 1). We called this group, therefore, the *categorically inoperable group*. This experience led us to conclude that radical mastectomy is futile in such cases. There are several types of cases in this group regarding which some discussion is desirable.

The group of cases with edema of the skin has especially interested us. I have already discussed the pathologic significance of this important clinical sign. In order to determine as accurately as possible the clinical significance of edema of the skin we classified the cases in which the phenomenon was present into two groups: (1) those in which the extent of the edema was limited to less than one third of the skin over the breast, and (2) those in which it extended over a larger area. The group of 41 cases included in table 1 were all of this latter type. When this extensive edema is interpreted in terms of the presence of carcinoma emboli in the subdermal lymphatics throughout the whole edematous area it is apparent why even the most radical surgical treatment always fails to cure.

The so-called inflammatory type of carcinoma of the breast is another type of incurable carcinoma which merits special consideration. In recent years this acute and fatal form of the disease has been well described by American and German writers, particularly Lee and Tannenbaum¹⁵ and Taylor and Meltzer.¹⁶

In our series of cases there were 28 patients with the inflammatory type of carcinoma. In 20 of them radical mastectomy was performed. In half of these there was known local recurrence, and all succumbed to their disease within a relatively short time after operation. It is understandable why this experience led us to place this type of case in the categorically inoperable group.

Another group of cases in our series in which the results of surgery were disastrous was that in which carcinoma of the breast occurred during pregnancy or lactation. Carcinoma occurring in the breast at this time, of course, shares the tremendous growth stimulus which physiologic need imparts, and it is only reasonable to expect the disease to be exceptionally malignant. Recently, however, Harrington¹⁷ has reported results in a much larger group of cases than ours from the

TABLE 1.—Results of Radical Mastectomy in Categorically Inoperable Groups of Cases

Clinical Group	Number of Cases	5 Year Local Recurrence		5 Year Clinical Cures, Number
		Number	Percentage

* Recurrence after six years.

Mayo Clinic, which give a more hopeful picture. While all except 1 of our group of patients had axillary metastases, 15.2 per cent of his did not have them. Sixty-one per cent of these patients who did not have metastases were still alive five years after operation. In view of Harrington's experience it may be that our group of cases was a particularly unfortunate one and that radical mastectomy is justified in these patients, provided, of course, that the disease is locally operable.

The relationship of the age of the patient to her chance of cure is a separate question, although again no doubt in some way dependent on physiologic differences. There is a widely held impression that carcinoma of the breast is incurable in young women. This is certainly incorrect. Taylor¹⁸ showed that the disease indeed tends to be more malignant in youth, but in carcinomas of the breast of comparable extent and equal grade of malignancy, age alone does not affect curability. De Cholnoky¹⁹ collected reports of a total

of 73 cases in women under 30: The five year survival rate was 40.8 per cent. On the other hand, most observers are agreed that in the aged, carcinoma of the breast usually progresses more slowly and is therefore more amenable to surgical attack. With modern surgical methods women in the seventies and eighties stand operation well, and although common sense may limit somewhat the extent of the operation, it is from every point of view preferable to radiation in patients in whom the disease is locally operable.

In our study of operability, Dr. Stout and I also worked out the significance, in our data, not only of a whole series of single clinical signs of the local extent of carcinoma of the breast, but of combinations of these various clinical signs. It was found that very few patients who showed certain combinations of signs of advanced local disease were cured by radical mastectomy. For example, patients with even a limited amount of edema of the skin of the breast and solid fixation of the carcinoma to the chest wall were not cured.

From all of these correlations we drew up the following rule for judging operability in carcinoma of the breast: Women of all age groups who are in good enough general condition to run the risk of major surgery should be treated by radical mastectomy, except

TABLE 2.—Comparison of Results of Radical Mastectomy at the Massachusetts General Hospital

Period	Percentage of 5 Year Cures
1911-1914.....	27

as follows: (1) when the carcinoma is one which developed during pregnancy or lactation; (2) when extensive edema of the skin over the breast is present; (3) when satellite nodules are present in the skin over the breast; (4) when intercostal or parasternal tumor nodules are present; (5) when there is edema of the arm; (6) when proved supraclavicular metastases are present; (7) when the carcinoma is the inflammatory type; (8) when distant metastases are demonstrated; (9) when any two, or more, of the following signs of locally advanced carcinoma are present: (a) ulceration of the skin; (b) edema of the skin of limited extent (less than one third of the skin over the breast involved); (c) solid fixation of the tumor to the chest wall; (d) axillary lymph nodes measuring 2.5 cm., or more, in transverse diameter, and proved to contain metastases by biopsy, and (e) fixation of axillary lymph nodes to the skin or the deep structures of the axilla.

If these criteria had actually been followed in judging operability in the six hundred and forty radical mastectomies in our case series, a total of 109 of the patients would not have been operated on. Yet the number of patients permanently cured would not have been decreased by a single one.

We presented this rule for judging the operability of carcinoma of the breast not as an inflexible edict, but merely as a tentative guide drawn from the experience of what actually happened in the Presbyterian Hospital series of cases. It is a pragmatic rule which was true for our hospital during the past generation.

We are already inclined to modify its first provision regarding the treatment of the disease in pregnancy or lactation. We suspect, however, that the rule as a whole will hold fairly true in the future, because whenever we have violated it in deciding whether or not to perform radical mastectomy during recent years we have failed to cure the patient.

Wells²⁰ has applied our method of studying the correlation between clinical signs and end results to the data on carcinoma of the breast of the Hartford Hospital. His observations are almost identical with ours.

Portmann²¹ has also worked out a series of criteria for determining operability which have been helpful in deciding the choice of treatment at the Cleveland Clinic. Although his criteria are less specific than ours, they also recognize the importance of edema of the skin and of fixation of the tumor to the chest wall and the hopelessness of the inflammatory type of carcinoma.

At the Massachusetts General Hospital, Simmons and Taylor²² have given special attention to the proper selection of cases for operation, and have evolved the following rule:

Carcinoma of the breast is operable when the disease is confined to the breast, or to the breast and axilla. The primary tumor must be movable in relation to the chest wall, and must not present extensive skin involvement, skin metastasis, or the subepidermal infiltration known as "inflammatory" carcinoma. The axillary nodes must be movable in relation to the chest wall and great vessels, and these nodes must be few in number. There must be no evidence of disease in the supraclavicular areas or in the opposite axilla, nor metastatic disease in the lungs, pleura, liver, or skeleton.

The experience at the Massachusetts General Hospital is of special importance as illustrating the remarkable improvement in the results of radical mastectomy during the past generation that has resulted from more critical selection of cases for operation. When Greenough²³ began his study of the 1911 end results in cancer of the breast in that clinic he had the wisdom and foresight to draw up a well considered plan for classifying the cases and reporting the end results. This plan has been followed ever since at the Massachusetts General Hospital, with the result that the data on end results from this hospital, computed in a strict and uniform manner from 1911 to 1935, are the most complete and accurate available anywhere in the world.²⁴ The five year cure rates in this series of cases are shown in table 2.

Throughout all these years there has been no essential change in the technic of radical mastectomy at the Massachusetts General Hospital. Yet the rate of cure has almost doubled. Grantley Taylor, who carries on the work with carcinoma of the breast begun by Greenough and Simmons, stated²⁵: "We have narrowed our indications for operation very considerably and this

accounts largely for the apparent improvement in our end results.

It is understandable why the past generation of surgeons, in trying to find out what the newly devised operation of radical mastectomy could accomplish, operated on all patients irrespective of the stage of their disease. Today, however, enough has been learned about what can be accomplished with the operation to limit its use sharply. Careful selection of cases for radical mastectomy is not an indication of timidity on the part of the modern surgeon, but rather an index of the extent of his knowledge of carcinoma of the breast. The truth is that it is not only a waste of time and energy to perform radical mastectomy on patients whose disease is incurable; the operation probably spreads the disease and shortens life in these patients. This is a difficult point to prove statistically, but all surgeons who have operated on these far advanced cases have seen widespread generalized metastases develop soon afterward, just as if a shower of carcinoma emboli had been set free by the operation. This, of course, is what a surgeon should expect if his dissection is carried into or through carcinoma. The surgeon's knife is a double-edged sword that can do harm as well as good.

Any plan for the selection of patients for radical mastectomy should emphasize a careful preoperative search for distant metastases. This should include inquiry regarding back and leg pain signaling the presence of metastases in the spine or pelvis, and palpation of the supraclavicular areas, the opposite breast and axilla, and the liver. Roentgenograms should be made of the chest, and at least of the skull, the shoulder girdle, the entire spine, the pelvis and the upper part of the femurs. Every now and then distant metastases will be found by these methods, even though the primary carcinoma in the breast remains small and entirely operable. Radiation is, of course, the proper treatment for these patients.

RADICAL MASTECTOMY

The next step in improving the surgical attack on carcinoma of the breast is to popularize the *radical* mastectomy. This operation, devised independently by two American surgeons, Halsted and Willy Meyer,²⁶ a half century ago, has never been universally adopted. It is too extensive and tedious a dissection to win the approval of hasty or timid surgeons. The operation is not a difficult or dangerous one, but surgeons must believe in it to be willing to devote the time and energy that its performance demands, and there have been too many unbelievers.

Both Halsted and Willy Meyer changed and improved their technics as the operation evolved in their hands. They both soon came to emphasize four common principles: (1) excision of the skin over the whole breast, covering the defect which remains with a Thiersch graft when necessary; (2) excision of both pectoral muscles; (3) a complete axillary dissection, and (4) removal of the excised tissues in one block.

Since the operation is an extensive one, combining a series of related regional dissections, it is only natural that many different technics for it have been devised.

The adequacy of any special technic should be judged in terms of the fundamental attitude with which the surgeon plans and carries out his surgical attack. First of all, he must be unwilling to compromise by limiting his operation in any way, provided that his patient can

stand a radical operation. Every single carcinoma cell must be removed if cure is to be achieved, and a thoroughly radical operation offers the best chance of accomplishing this. Incomplete operations are unfortunately still widely done, and when they fail to cure, as they usually do, they discredit the surgical attack on the disease in the minds of both laymen and physicians.

The surgeon who performs radical mastectomy should know how to cut and how to manage thin skin flaps, as well as how to cover a defect on the chest wall with a skin graft. This ability frees him from the necessity of having to limit the amount of skin and subcutaneous tissue which he removes so that he can close the wound. He can disregard the problem of closure and think only of what needs to be sacrificed to cure the carcinoma. In some patients with large breasts skin grafting may not be required, but certainly when the breast is small and the patient herself not obese, a thoroughly radical operation will leave a defect on the chest wall which requires a skin graft.

There are still surgeons who do not sacrifice the pectoralis minor muscle, although it is anatomically impossible to carry out a complete axillary dissection unless the muscle is sacrificed. Both Greenough²⁷ and White²⁸ showed that when this muscle is spared the rate of cure is lower.

A second fundamental requirement of a surgeon who performs radical mastectomy is that he know how to operate gently and with good hemostasis. The late George Crile once classified surgeons as the *carnivorous* type who stretch, tear and crush the tissues, and the *herbivorous* type who dissect gently. There is no place where the latter type of technic pays better dividends than in radical mastectomy. In our microscopic studies we have often seen small emboli of carcinoma cells in the lymphatics of the breast and in the peripheral sinuses of lymph nodes. It is easily understood how such emboli can be set free by rough operating and escape into the venous blood stream or be implanted in the wound.

Great care should therefore be taken not to press on or squeeze the breast and to avoid traction on it. All manipulations should be as gentle as possible. Exact hemostasis is required because without it the surgeon loses sight of fascial planes and misses important anatomic landmarks. In the dissection of the axilla perfect hemostasis and sharp dissection with knife and forceps are necessary if all lymph nodes are to be removed and the task accomplished without crushing them and perhaps smearing carcinoma cells throughout the area. White²⁹ has recently reported an example of the implantation of carcinoma cells in the donor area of a skin graft on the leg, illustrating the ease with which carcinoma cells can be implanted.

There are of course a number of good technics for radical mastectomy based on the general principles which I have outlined. These have been evolved by the pupils of both Willy Meyer and Halsted. Halsted made a special effort to teach his residents to do the operation well. A number of them became heads of departments of surgery and their prestige helped to

make the operation known. In Boston, J. C. Warren adopted Willy Meyer's version of the operation at an early date, modified its technic and passed on his interest in it to Greenough, who perfected the method that has been used at the Massachusetts General Hospital for a long period of years. Grantley Taylor³⁰ has published a complete description of the Greenough technic.

In our own surgical attack on carcinoma of the breast we have followed the principle that the disease is such a formidable enemy, even when apparently confined within operable limits, that it is our duty to make our dissection as radical as possible. By this we mean that we remove as much tissue from the chest wall and axilla as we dare, without unreasonable danger to the patient's life or interference with thoracic and arm function. I have recently described my technic,³¹ which is based on the Halsted operation but includes many details derived from the technic of the late George H. Semken, who was a pupil of the Willy Meyer school.

In my operation the skin incision is planned solely from the viewpoint of adequate local removal of the suspected tissues and not with any reference to closing the wound. We know that we can cover a defect of any size by skin grafting.

Our skin flaps are much thinner than in the usual radical mastectomy because we know that it is necessary to make them very thin if the inclusion of breast tissue is to be avoided. The breast is derived embryologically from the skin glands and lies only a few millimeters below its surface. Surgeons should not delude themselves that they are removing all the breast tissue in the operative specimen, if their skin flaps are a centimeter or more in thickness. Our skin flaps include only the skin itself, with its dermal glands and small blood vessels, and the thin layer of fat and areolar tissue lying above the superficial layer of the superficial fascia. The dissection elevates the skin flaps from this delicate fascial layer, leaving behind the large thin-walled blood vessels and their accompanying lymphatics, as well as the breast tissue, which lie below the fascia.

Another feature of our operation is that it is so planned as to avoid traction on the breast as it is being dissected from the chest wall or in the exposure of the axillary structures. As soon as the skin flaps have been dissected up and the attachment of the pectoralis major muscle to the arm and clavicle severed, this muscle together with the overlying breast and subcutaneous tissue is dissected off of the chest wall, beginning at the midline. The whole specimen is allowed to fall laterally of its own weight. No traction on it is required. The surgeon's access to the axilla is greatly facilitated by first removing the muscles and the breast from the chest wall. A thorough axillary dissection is more easily carried out.

In this axillary dissection we regularly sacrifice the subscapular vessels because this makes for a cleaner dissection of the subscapular region. In cases in which the axillary nodes are clinically involved we also sacrifice the thoracodorsal nerve, rather than to preserve it and dissect it out from among the subscapular lymph nodes.

We take great care not to use too much tension in closing the wound, because this leads to necrosis and poor wound healing, which in turn predispose to the

later development of edema of the arm. In the great majority of our cases a defect remains which we close with an immediate Thiersch graft.

Our operation requires about five hours to perform. With good anesthesia—we use "pentothal sodium" and nitrous oxide—and proper care in the avoidance of shock, this is a perfectly safe operating time.

We hasten to add that we have no final statistical proof that this ultraradical type of mastectomy gives a higher cure rate than other somewhat less radical technics. We are inclined to believe, however, that this kind of operation has some advantages as regards local recurrence.

VOGUE OF LOCAL MASTECTOMY

From time to time some doubting Thomas of a surgeon raises his voice in favor of local mastectomy as a substitute for radical mastectomy. The argument advanced is usually along the line that carcinoma of the breast that has metastasized to the axilla cannot be cured anyway and that mere removal of the breast will cure carcinoma limited to the mammary gland itself.
